# **Moscow ML Library Documentation**

Version 2.00 of June 2000

Peter Sestoft, Royal Veterinary and Agricultural University, Copenhagen, Denmark Claudio Russo, Cambridge University, Cambridge, United Kingdom Sergei Romanenko, Russian Academy of Sciences, Moscow, Russia

#### This document

This manual describes the Moscow ML library, which includes parts of the SML Basis Library and several extensions. The manual has been generated automatically from the commented signature files.

# Alternative formats of this document

# Hypertext on the World-Wide Web

The manual is available at http://www.dina.kvl.dk/~sestoft/mosmllib/ for online browsing.

# Hypertext in the Moscow ML distribution

The manual is available for offline browsing at mosml/doc/mosmllib/index.html in the distribution.

The manual is available also in interactive mosml sessions. Type help "lib"; for an overview of built-in function libraries. Type help "fromstring"; for help on a particular identifier, such as fromstring. This will produce a menu of all library structures which contain the identifier fromstring (disregarding the lowercase/uppercase distinction): On-line help in the Moscow ML interactive system

Bool.tromString	Char.fromString	Date.fromString	Int.fromString	Path.fromString	Real.fromString	String.fromString	Time.fromString	Word.fromString	Word8.fromString	
Val	val	val	val	val	val	val	val	val	val	
7	7	~	4	2	9	7	80	9	10	
_	_	_	_	_	_	_	_	_	_	

Choosing a number from this menu will invoke the help browser on the desired structure, e.g. Int.

The Moscow ML home page is http://www.dina.kvl.dk/~sestoft/mosml.html

2 APPLESCRIPT

### Module AppleScript

```
AppleScript -- Apple MacOS scripting
type OSALD
type OSAerr = int
exception AppleScriptErr of OSAerr * string
val as_compile : string -> OSALD
val as_dispose : OSALD -> unit
val as_tun_script : OSALD -> string
val as_tun_text : string -> string
```

These Mac specific functions provide the capability to compile and run AppleScript programs.

The exception AppleScriptErr is raised in the event of an error.

[as\_compile str] compiles AppleScript source code text, returning an abstract token of type OSAID. This token may be used to run the script. The token may be used repeatedly until it is returned with as\_dispose or until mosml exits.

[as dispose tok] disposes of the resources associated with the OSAID token so that they may be reused by the AppleScript system. AppleScriptErr is raised upon any attemp to reuse a disposed token.

[as\_run\_script tok] runs the script associated with the token. This typically involves AppleBvent communication with other programs running on the Mac, or networked Macs. The AppleScript result is returned as a string.

[as\_run\_text str] compiles and runs the AppleScript source code text, disposing all resources allocated in the process, and returns the AppleScript result as a string.

#### **Module Array**

```
Array -- SML Basis Library
```

prim\_EQtype 'a array

: int

val maxLen

['ty array] is the type of one-dimensional, mutable, zero-based constant-time-access arrays with elements of type 'ty. Type 'ty array admits equality even if 'ty does not. Arrays al and a are equal if both were created by the same call to a primitive (array, tabulate, fromList).

Some functions work on a \*slice\* of an array:

The slice (a, i, SOWE n) denotes the subarray a[i..i+n-1]. That is, a[i] is the first element of the slice, and n is the length of the slice. Valid only if 0 <= i <= i+n <= length a.

The slice (a, i, NONE) denotes the subarray a[i.length a-1]. That is, the slice denotes the suffix of the array starting at i. Valid only if 0 <= i <= length a. Equivalent to (a, i, SOME(length a - i)).

slice

(a, 0, NONE) the whole array a[0.len-1]

(a, 0, SOME n) a left subarray (prefix) a[0.len-1]

(a, i, NONE) a sight subarray (suffix) a[i.len-1]

(a, i, SOME n) a general slice

[maxLen] is the maximal number of elements in an array.

[array(n, x)] returns a new array of length n whose elements are all x. Raises Size if n<0 or n>maxLen.

[tabulate(n, f)] returns a new array of length n whose elements are f 0, f 1, ..., f (n-1), created from left to right. Raises Size if n<0 or n>maxLen.

[fromList xs] returns an array whose elements are those of xs. Raises Size if length xs > maxLen.

[length a] returns the number of elements in a.

[sub(a, i)] returns the i'th element of a, counting from 0. Raises Subscript if i<0 or i>=length a. To make 'sub' infix, use

the declaration

infix 9 sub

[update(a, i, x)] destructively replaces the i'th element of a by Raises Subscript if i<0 or i>=length a.

[extract(a, i, NONE)] returns a vector of the elements a[i..length a-1] of a. Raises Subscript if i<0 or i>length a.

[extract(a, i, SOME len)] returns a vector of the elements a[i..i+len-1] of a. Raises Subscript if i<0 or len<0 or i+len>length a or

[copy(src, si, len, dst, di]] destructively copies the slice (src, si, len) to dst, starting at index di. More precisely: If len-NOWRs and n=length src, it copies src[si.n.-l] to dst[di.di+n-si]. If len=SOWE k, it copies src[si.si+k-1] to dst[di.di+k-1]. Works also if src and dst are the same and the segments overlap. Raises Subscript if si < 0 or di < 0, or if len=NONE and di + length src - si > length dst, or if len=SOME k and k < 0 or si + k > length src or di + k > length dst. len>Vector.maxLen.

[copyWec(src, si, len, dst, di)] destructively copies the slice (src, si, len) to dst, starting at index di. More precisely: If len-MONB and nelength src, it copies src[si...nl] to dst[di.di+n-si]. If len-SOWB k, it copies src[si..si+k-1] to dst[di.di+k-1]. Works also if src and dst are the same and the segments overlap. Raises Subscript if si < 0 or di < 0, o, or if len-NONB and di + length src - si > length dst, or if len-SOME k and k < 0 or si + k > length src or di + k > length dst.

That is, [fold] f e a] folds function f over a from left to right. That i computes f(a[len-1], f(a[len-2], ..., f(a[l], f(a[0], e)) ...)), where len is the length of a.

That is, [foldr f e a] folds function f over a from right to left. computes f(a[0], f(a[1], ..., f(a[len-2], f(a[len-1], e)) where len is the length of a.

(app f a) applies f to a[j] for  $j=0,1,\ldots,l$ ength a-1.

[modify f a] applies f to a[j] and updates a[j] with the result f(a[j]) for j=0,1,...,length a-1.

The following iterators generalize the above ones in two ways:

. the index j is also being passed to the function being iterated; the iterators work on a slice (subarray) of an array.

[foldli f e (a, i, SOME n)] folds function f over the subarray a[i..i+n-1] from left to right. That is, computes f(i+n-1, a[i+n-1], f(..., f(i+1, a[i+1], f(i, a[i], e)) ...)). Raises Subscript if ie(0 or n<0 or i+n > length ai.

 $\overset{\cdot }{\widehat{\phantom{a}}}\overset{\cdot }{\widehat{\phantom{a}}}$ [foldli f e (a, i, NONE)] folds function f over the subarray a di..len-l] from left to right, where len = length a. That is, computes f(len-1, a[len-1], f(i..., f(i+1, a[i+1], f(i, a[i], e)) Raises Subscript if i<0 or i > length a.

[foldri f e (a, i, SOME n)] folds function f over the subarray a[1.14n-1] from right to left. That is, computes f(i, a[1], f(i+1, a[i+1], ..., f(i+n-1, a[i+n-1], e) ...)). Raises Subscript if i<0 or n<0 or i+n > length a.

[foldri f e (a, i, NONE)] folds function f over the subarray ali..den-1] from right to left, where len = length a. That is, computes f(i, ali) f(i+1, ali+1) ..., f(len-1, allen-1], e) ...)). Raises Subscript if i<0 or i > length a.

[appi f (a, i, SOME n)] applies f to successive pairs (j, a[j]) for  $j=i,i+1,\ldots,i+n-1$ . Raises Subscript if i<0 or n<0 or i+n > length a.

ARRAY

S

[appi f (a, i, NOME)] applies f to successive pairs (j, a[j]) for j=1,1+1,...len-1, where len = length a. Raises Subscript if i<0 or i > length a.

[modifyi f (a, i, SOME n)] applies f to (j, a[j]) and updates a[j] with the result f(j, a[j]) for j=i,i+1,...,i+n-1. Raises Subscript if i<0 or n<0 or i+n > length a.

[modifyi f (a, i, NONE)] applies f to (j, a[j]) and updates a[j] with the result f(j, a[j]) for j=i,i+1,...,len-1. Raises Subscript if i<0 or i > length a.

ARRAY2

#### Module Array2

Array2 -- SML Basis Library

eqtype 'a array

```
/ unit
                             : int * int * '_a -> '_a array
: '_a list list -> '_a array

                                                                                                                                                                                                                                                                                                                                                                                                                                                     val
val
                                                                                                    val
                                                                                                                     val
                                                                                                                                         val
                                                                                                                                                                         val
                                                                                                                                                                                                                           val
                                                                                                                                                                                                                                            Val
                                                                                                                                                                                                                                                                                                                                val
                                                                                                                                                                                                                                                                                                                                                                                    val
                                                                                                                                                                                                                                                                                                                                                                                                     val
val
```

['ty array] is the type of two-dimensional, mutable, zero-based constant-time-access arrays with elements of type 'ty.

Type 'ty array admits equality even if 'ty does not'. Arrays al and a2 are equal if both were created by the same call to one of the primitives array, fromList, and tabulate.

[traversal] is the type of traversal orders: row major or column major.

[RowMajor] specifies that an operation must be done in row-major order, that is, one row at a time, from top to bottom, and from left to right within each row. Row-major traversal visits the elements of an (m,n)-array with m rows and n columns in this

 $(0,0), (0,1), (0,2), \dots, (0,n-1), (1,0), (1,1), (1,2), \dots, (1,n-1),$ 

that is, in order of lexicographically increasing (i, j). In Moscow ML, row-major traversal is usually faster than column-major

traversal

[ColMajor] specifies that an operation must be done in column-major order, that is, one column at a time, from left to right, and from top to bottom within each column. Column-major traversal visits the elements of an (m,n)-array with m rows and n columns in this order:

(0,0), (1,0), (2,0), ..., (m-1,0), (0,1), (1,1), (2,1), ..., (m-1,1),

that is, in order of lexicographically increasing (j, i).

[array(m, n, x)] returns a new m \* n matrix whose elements are all x. Raises Size if n<0 or m<0.

[fromList xss] returns a new array whose first row has elements

Y2

1

```
xs1, second row has elements xs2, ..., where xss = [xs1,xs2,...,xsm]. Raises Size if the lists in xss do not all have the same length.
```

[tabulate RowMajor (m, n, f)] returns a new m-by-n array whose elements are f(0,0), f(0,1), ..., f(0, n-1), f(1,0), f(1,1), ..., f(1, n-1),

f(m-1,0), (m-1, n-1) created in row-major order: f(0,0), f(0,1), ..., f(1,0), f(1,1), .... Raises Size if n<0 or m<0. [tabulate ColMajor (m, n, f)] returns a new m-by-n array whose elements are as above, but created in the column-major order: f(0,0), f(1,0), ..., f(0,1), f(1,1), ... Raises Size if n<0 or m<0.

[dimensions a] returns the dimensions  $(\mathfrak{m},\ n)$  of a, where  $\mathfrak{m}$  is the number of rows and n the number of columns.

[nCols a] returns the number of n of columns of a.

nRows a] returns the number of m of rows of a.

[sub(a, i, j)] returns the i'th row's j'th element, counting from 0. Raises Subscript if i<0 or j<0 or i>=m or j>=n where (m,n) = dimensions a.

[update(a, i, j, x)] destructively replaces the (i,j)'th element of a by x. Raises Subscript if i<0 or j<0 or i>=m or j>=n where (m,n) = dimensions a.

[row (a, i)] returns a vector containing the elements of the ith row of a. Raises Subscript if i < 0 or i >= height a.

[column (a, j)] returns a vector containing the elements of the jth column of a. Raises Subscript if j < 0 or j >= width a.

[app RowMajor f a] applies f to the elements a[0,0], a[0,1], ..., a[0,n-1], a[1,0], ..., a[m-1, n-1] of a, where (m, n) = dimensions a.

[app ColMajor f a] applies f to the elements a[0,0], a[1,0], ..., a[n-1,0], a[0,1], a[1,1], ..., a[m-1, n-1] of a, where (m, n) = dimensions a.

[modify RowNajor f a] applies f to the elements a[0,0], a[0,1], ..., a[0,1-1], a[1,0], ..., a[m-1, n-1] of a, updating each element with the result of the application, where (m, n) = dimensions a.

[modify ColMajor f a] applies f to the elements a[0,0], a[1,0], element with a[0,1], a[1,1], ..., a[m-1, n-1] of a, updating each element with the result of the application, where (m, n) = dimensions a.

[fold RowMajor f b a] folds f left-right and top-down over the elements of a in row-major order. That is, computes f(a[m-1, n-1], f(a[m-1, n-2]), ..., f(a[0,1], f(a[0,0], b)) ...)) where (m, n) = dimensions a.

[fold ColMajor f b a] folds f left-right and top-down over the elements of a in column-major order. That is, computes f(a[m-1, n-1], f(a[m-2, n-1], ..., f(a[1,0], f(a[0,0], b)) ...)) where (m, n) = dimensions a.

The following iterators generalize the above ones in two ways:

\* the indexes i and j are also being passed to the function: \* the iterators work on a region (submatrix) of a matrix. [region] is the type of records { base, row, col, nrows, ncols } determining the region or submatrix of array base whose upper left corner has index (row, col).

 $\infty$ 

If nrows = SOME r, then the region has r rows: row, row+1, ..., row+r-1. If nrows = NONE, then the region extends to the bottom of the matrix. The field nools similarly determines the number of columns.

A region is valid for an array with dimensions (m, n) if (1) either nrows = NONE and 0 <= row <= m or nrows = SONE r and 0 <= row + r <= m and (2) either ncols = NONE and 0 <= col <= n or ncols = SOME c and 0 <= col <= col + c <= n.

[appi RowMajor f reg] applies f to (i, j, a[i, j]) in order of lexicographically increasing (i, j) within the region reg. Raises Subscript if reg is not Note that app tr f a is equivalent to appi tr (f o #3) {base=a, row=0, col=0, nrows=NONE, ncols=NONE}

[appi ColMajor f reg] applies f to (i, j, a[i, j]) in order of lexicographically increasing (j, i) within the region reg. Raises Subscript if reg is not valid.

[modifyi RowMajor f reg)] applies f to (i, j, ali, j]) in order of statoographically increasing (i, j) within the region reg. Raises Subscript if reg is not valid. Note that modify tr f a is equivalent to modifyi (f o #3) {base=a, row=0, col=0, nrows=NONE, ncols=NONE}).

[modifyi ColMajor f reg)] applies f to (i, j, ali, j) in order of lexicographically increasing (j, i) within the region reg. Raises Subscript if reg is not valid.

[foldi RowMajor f b a] folds f over (i, j, a[i, j]) in row-major order within the region reg, that is, for lexicographically increasing (i, j) in the region. Raises Subscript if reg is not valid.

[fold: ColMajor f b a] folds f over (i, j, a[i, j]) in column-major order within the region reg, that is, for lexicographically increasing (j, i) in the region. Raises Subscript if reg is not valid.

[copy { src, dst, dst\_row, dst\_col }] copies the region determined by src to array dst such that the upper leftmost corner of src is copied to dst[dst\_row, dst\_col]. Works correctly even when src and dst are the same and the source and destination regions overlap. Raises Subscript if the src region is invalid, or if src translated to (dst\_row, dst\_col) is invalid for dst.

ARRAYSORT

0

#### **Module Arraysort**

Arraysort -- Quicksort for arrays, from SML/NJ library

val sort : ('a \* 'a -> order) -> 'a Array.array -> unit
val sorted : ('a \* 'a -> order) -> 'a Array.array -> bool

[sort ordr arr] sorts array arr in-place, using ordering relation ordr

[sorted ordr arr] returns true if the elements of array arr is appear in (weakly) increasing order, according to ordering ordr

#### Module BinIO

BinIO -- SML Basis Library

type vector = Word8Vector.vector = Word8.word type elem

Binary input

type instream

: instream -> vector option : instream -> elem option : instream \* int -> vector : instream -> bool -> elem option instream -> unit instream -> vector string -> instream instream -> vector instream inputAll inputNoBlock: input1 inputN endOfStream lookahead openIn closeIn input val val val val val val

Binary output

type outstream

: string -> outstream : string -> outstream : outstream -> unit openOut openAppend closeOut output val val val val

outstream \* vector -> unit outstream \* elem -> unit outstream -> unit

outputl flushOut

This structure provides input/output functions on byte streams. The functions are state-based: reading from or writing to a stream changes the state of the stream. The streams are buffered: output to a stream may not immediately affect the underlying file or device.

[instream] is the type of state-based byte input streams.

[outstream] is the type of state-based byte output streams.

[elem] is the type Word8.word of bytes.

[vector] is the type of Word8Vector.vector (byte vectors).

BYTE INPUT:

[openIn s] creates a new instream associated with the file named Raises Io.Io is file s does not exist or is not accessible.

[closeIn istr] closes stream istr. Has no effect if istr is closed already. Further operations on istr will behave as if istr is at end of stream (that is, will return "" or NONE or true).

[input istr] reads some elements from istr, returning a vector v of those elements. The vector will be empty (size  $\mathbf{v}=0$ ) if and only if istr is at end of stream or is closed. May block (not return until data are available in the external world).

inputAll istr] reads and returns the vector v of all bytes remaining in istr up to end of stream. [imputNoBlock istr] returns SOME(v) if some elements v can be read without blocking; returns SOME(") if it can be determined without blocking that istr is at end of stream; returns NONE otherwise. If istr does not support non-blocking input, raises o. NonblockingNotSupported.

input1 istr] returns SOME(e) if at least one element e of istr is

available; returns NONE if istr is at end of stream or is closed;

BINIO

blocks if necessary until one of these conditions holds.

=

[imputN(istr, n)] returns the next n bytes from istr as a vector, if that many are available; returns all remaining bytes if end of stream is reached before n bytes are available; blocks if necessary until one of these conditions holds.

[endOfStream istr] returns false if any elements are available in istr; returns true if istr is at end of stream or closed; blocks if necessary until one of these conditions holds.

[lookahead istr] returns SOME(e) where e is the next element in the stream; returns NONE if istr is at end of stream or is closed; blocks if necessary until one of these conditions holds. Does not advance the stream.

BYTE OUTPUT:

[openOut s] creates a new outstream associated with the file named s. If file s does not exist, and the directory exists and is writable, then a new file is created. If file s exists, it is truncated (any existing contents are lost).

13 [openAppend s] creates a new outstream associated with the file named s. If file s does not exist, and the directory exists and writable, then a new file is created. If file s exists, any existing contents are retained, and output goes at the end of the [closeOut ostr] closes stream ostr; further operations on ostr (except for additional close operations) will raise exception Io.Io.

output(ostr, v)] writes the byte vector v on outstream ostr.

output1(ostr, e)] writes the byte e on outstream ostr.

[flushOut ostr] flushes the outstream ostr, so that all data written to ostr becomes available to the underlying file or device.

The functions below are not yet implemented:

[setPosIn(istr, i)] sets istr to the position i. Raises Io.Io if not supported on istr. getPosIn istr] returns the current position of istr. Raises Io.Io if not supported on istr.

endPosIn istr] returns the last position of istr.

[getPosOut ostr] returns the current position in stream ostr. Raises Io.Io if not supported on ostr.

endPosOut ostr] returns the ending position in stream ostr. Raises Io.Io if not supported on ostr.

ಭ setPosOut(ostr, i)] sets the current position in stream to ostr i. Raises Io.Io if not supported on ostr.

mkInstream sistr] creates a state-based instream from the functional instream sistr. getInstream istr] returns the functional instream underlying the state-based instream istr setInstream(istr, sistr)] redirects istr, so that subsequent input is taken from the functional instream sistr.

[mkOutstream sostr] creates a state-based outstream from the outstream sostr.

[getOutstream ostr] returns the outstream underlying the state-based outstream ostr.

[setOutstream(ostr, sostr)] redirects the outstream ostr so that subsequent output goes to sostr.

Module Binarymap

BINARYMAP

13

Binarymap -- applicative maps as balanced ordered binary trees From SML/NJ lib 0.2, copyright 1993 by AT&T Bell Laboratories Original implementation due to Stephen Adams, Southampton, UK

type ('key, 'a) dict

                                                                                                                                                  numItems
listItems
                                                                                                                                                                                                                                                                                                                                                   val transform
      val mkDict val insert val insert val ind val peek val remove val numItems val app val app val foldr val foldr val map
```

[('key, 'a) dict] is the type of applicative maps from domain type 'key to range type 'a, or equivalently, applicative dictionaries with keys of type 'key and values of type 'a. They are implemented as ordered balanced binary trees.

[mkDict ordr] returns a new, empty map whose keys have ordering

[insert(m, i, v)] extends (or modifies) map m to map i to v.

[find (m, k)] returns v if m maps k to v; otherwise raises NotFound.

[peek(m, k)] returns SOME v if m maps k to v; otherwise returns NONE.

[remove(m, k)] removes k from the domain of m and returns the modified map and the element v corresponding to k. Raises NotFound if k is not in the domain of m.

[numItems m] returns the number of entries in m (that is, the size of the domain of m). [listItems m] returns a list of the entries  $(k,\ v)$  of keys k and the corresponding values v in m, in order of increasing key values. [app f m] applies function f to the entries (k, v) in m, in increasing order of k (according to the ordering ordr used to create the map or dictionary).

ij. [revapp f m] applies function f to the entries (k, v) in m, decreasing order of k.

s [fold] f e m] applies the folding function f to the entries  $(k,\ in\ n,\ in\ increasing\ order\ of\ k.$  [foldr f e m] applies the folding function f to the entries  $(k,\ v)$  in m, in decreasing order of k.

[map f m] returns a new map whose entries have form  $(k,\ f(k,\nu))$  , where  $(k,\ \nu)$  is an entry in m.

[transform f m] returns a new map whose entries have form  $(k,\ f\ v)\,,$  where  $(k,\ v)$  is an entry in m.

BINARYSET

#### Module Binaryset

4

Binaryset -- sets implemented by ordered balanced binary trees From SML/NJ lib 0.2, copyright 1993 by AT&T Bell Laboratories Original implementation due to Stephen Adams, Southampton, UK

type 'item set

exception NotFound

['item set] is the type of sets of ordered elements of type 'item. The ordering relation on the elements is used in the representation of the set. The result of combining two sets with different underlying ordering relations is undefined. The implementation uses ordered balanced binary trees.

[empty ordr] creates a new empty set with the given ordering relation.

[singleton ordr i] creates the singleton set containing i, with the given ordering relation.

[add(s, i)] adds item i to set s.

[addList(s, xs)] adds all items from the list xs to the set s.

[retrieve(s, i)] returns i if it is in s; raises NotFound otherwise.

[peek(s, i)] returns SOME i if i is in s; returns NONE otherwise.

[isEmpty s] returns true if and only if the set is empty.

 $\lceil equal(sl,\ s2) \rceil$  returns true if and only if the two sets have the same elements.

[isSubset(s1, s2)] returns true if and only if s1 is a subset of s2.

[member(s, i)] returns true if and only if i is in s.

delete(s, i)] removes item i from s. Raises NotFound if i is not in s.

numItems s] returns the number of items in set s.

union(s1, s2)] returns the union of s1 and s2.

[intersection(s1, s2)] returns the intersectionof s1 and s2.

[difference(s1, s2)] returns the difference between s1 and s2 (that is, the set of elements in s1 but not in s2).

BINARYSET

15

[listItems s] returns a list of the items in set s, in increasing

(app f s] applies function f to the elements of s, in increasing

revapp f s] applies function f to the elements of s, in decreasing

set in increasing order.

[foldr f e s] applies the folding function f to the entries of the set in decreasing order.

[find  $p\ s$ ] returns SOWB i, where i is an item in s which satisfies p, if one exists; otherwise returns NONE.

16 BOOJ

#### Module Bool

Bool -- SML Basis Library
datatype bool = datatype bool
val not : bool -> bool
val toString : bool -> string
val fromString : string -> bool option
val scan : (char, 'a) StringCvt.reader -> (bool, 'a) StringCvt.reader

[bool] is the type of Boolean (logical) values: true and false.

[not b] is the logical negation of b.

[toString b] returns the string "false" or "true" according as b is false or true.

[fromString s] scans a boolean b from the string s, after possible initial whitespace (blanks, tabs, newlines). Returns (SOWE b) if s has a prefix which is either "false" or "true"; the value b is the corresponding truth value; otherwise NONE is returned.

[scan getc src] scans a boolean b from the stream src, using the stream accessor getc. In case of success, returns  $\mathrm{SOWE}(b, \, \mathrm{rst})$  where b is the scanned boolean value and rst is the remainder of the stream; otherwise returns  $\mathrm{NONE}$ .

17

#### Module Byte

BYTE

Byte -- SML Basis Library

val byteToChar : Word8.word -> Char.char
val charToByte : Char.char -> Word8.word .
val byteSOString : Word8Vector.vector -> String.string
val stringToBytes : String.string -> Word8Vector.vector .

val stringToBytes : String.string -> Word8Vector.vector

val unpackStringVec : Word8Vector.vector \* int \* int option -> string
val unpackString : Word8Array.array \* int \* int option -> string
val packString : Substring.substring \* Word8Array.array \* int -> unit

Conversions between bytes and characters, and between byte vectors

and strings (character vectors).

[byteToChar w] is the character corresponding to the byte w.

[charToByte c] is the byte corresponding to character c

[bytesToString  $\mathbf{v}$ ] is the string whose character codes are the bytes from vector  $\mathbf{v}$ .

[stringToBytes s] is the byte vector of character codes of the string s.

In Moscow ML, all the above operations take constant time. That is, no copying is done.

[unpackStringVec (v, i, NONE)] is the string whose character codes are the bytes of v[i..length v-1]. Raises Subscript if i<0 or i>length v. Equivalent to bytesToString(Word8Vector.extract (v, i, NONE)).

[unpackStringVec (v, i, SOME n)] is the string whose character codes are the bytes of v[i...i+n-1]. Raises Subscript if i<0 or n<0 or i+n>length v Equivalent to bytesToString(Word8Vector.extract (v, i, SOME n)).

[unpackString (a, i, NONE)] is the string whose character codes are the bytes of a[i..length a-1]. Raises Subscript if i<0 or i>length a. Equivalent to bytesToString(Word8Array.extract (v, i, NONE)).

[unpackString (a, i, SOWE n)] is the string whose character codes are the bytes of a[i..i+n-1]. Raises Subscript if i<0 or n<0 or i+n>length a Equivalent to bytesToString(Word8Array.extract (a, i, SOME n)).

[packString (ss, a, i)] copies the character codes of substring ss into the subarray a[i..1+n-1] where n = Substring.size ss. Raises Subscript if i.60 or i+n > length a. Equivalent to wordAnray.copyVec(src=s, si=si, len=SOME n, dst=a, di=i) When (s, si, n) = Substring.base ss.

CALLBACK

#### Module Callback

<u>×</u>

MLCallback -- registering ML values with C, and accessing C values from

Registering ML values for access from C code:

register : string -> 'a -> unit unregister : string -> unit isRegistered : string -> bool val register val

Accessing C variables and functions from ML:

type cptr

```
^
                                                       , b
, a5
: string -> cptr

: cptr -> 'b

: cptr -> 'al -> 'b

: cptr -> 'al -> 'a2 -> 'b

: cptr -> 'al -> 'a2 -> 'a3 -> 'b

: cptr -> 'al -> 'a2 -> 'a3 -> 'a4 -> 'b

: cptr -> 'al -> 'a2 -> 'a3 -> 'a4 -> 'b
  getcptr
                        app1
app2
app3
app4
app5
              var
  val
val
val
                                               val
val
```

á

REGISTERING ML VALUES FOR ACCESS FROM C CODE

This example shows how to register the ML function (fn n => 2 \* n) that it may be called from C code.

80

- Callback.register "myfun" (fn n => 2\*n) (0) The ML side registers the function:
- (1) The C side first obtains an ML value pointer:
- valueptr mvp = get\_valueptr("myfun");
- The C side then uses the ML value pointer to obtain an ML value, and uses it:
   callback(get\_value(mvp), Val\_long(42)); (2)

Calling get\_valueptr may cause the garbage collector to run; hence other live ML values must be registered as GC roots. The garbage collector will never move the ML value pointer; hence it need not be registered as a GC root in the C code. Operation (1) involves a callback to ML, and hence may be slow

Operation (2) is very fast. If the garbage collector is invoked between the call of get\_value() and the use of the ML value, then the value must be registered as a GC root. However, the idiom callback(get\_value(myp), argl); arglist safe provided the evaluation of argl does not provoke a garbage collection (e.g. if argl is a variable).

The C function get\_valueptr returns NULL if nam is not registered.

(and not reregistered) since myp was obtained; it raises exception Fall if myp itself is NULL. Every access to the ML value from C code should use the ML valueptr and get\_valueptr, otherwise the C code will not know when the value has been unregistered and possibly deallocated. The C function get\_value returns NULL if nam has been unregistered

The C functions (in mosml/src/runtime/callback.c)

void registervalue(char\* nam, value mlval)
void unregistervalue(char\* nam)
can be used just as Callback.register and Callback.unregister.

The C functions

```
value callbackptr (valueptr mvp, value argl) value arg2) value callbackptr2(valueptr mvp, value arg1, value arg2) value arg1, value arg2, value arg3) can be used for callback via an ML value pointer; they will raise
```

exception Fail if the ML function indicated by mvp has been unregistered

CALLBACK

19

[register nam v] registers the ML value v, so that it can be retrieved from C code under the name nam. If nam has previously been registered and then unregistered, it will be reregistered with the new value. The new value immediately becomes visible to the C the new value. The new value immediately becomes visible to side, both via get valueptr nam and via any ML value pointer previously obtained for nam. Raises exception Fail if nam he been registered and not yet unregistered.

[unregister nam] deletes the registration. This prevents C code from obtaining an ML value pointer for nam and from using an ML value pointer already obtained (but does not prevent C from attempting to use a stored ML value previously obtained with the help of the ML value pointer, which is unsafe anyway). Does nothing if nam is already unregistered. Raises exception Fail if nam has never been registered. [isRegistered nam] returns true if nam has been registered and not unregistered vet

Ä FROM ACCESSING REGISTERED C VARIABLES AND FUNCTIONS

This example shows how to register the C function

value silly\_cfun(value v)
{ return copy\_double(42.42 \* Double\_val(v)); }

so that it may be called from ML.

registercptr("mycfun", sillycfun); (0) The C side registers the function:

- via that pointer:

  val sillycfun = appl (getcptr "mycfun") : real -> real

  The type ascription is needed to ensure any type safety whatsoever.

  Mistakes in the types will lead to crashes, as usual with C. The ML side obtains a C pointer and defines an ML function (1)
  - To the ML side, the new ML function is indistinguishable from other ML functions val result = sillyfun(3.4) (2)

C function (in mosml/src/runtime/callback.c) The

void registercptr(char\* nam, void\*

is used to register C pointers for access from ML. Only pointers to static C variables, and C functions, should be registered. There is no way to unregister a C pointer.

[cptr] is the type of pointers to C variables and C functions.

registered (by the C side) under the name nam. Raises exception Fail if the name nam has not been registered. getcptr nam] returns a pointer to the C variable or function

var cptr] returns the value of the C variable associated with cptr.

appl optr argl] applies the C function associated with optr to argl

t cptr app2 cptr arg1 arg2] applies the C function associated with (argl, arg2)

[app3 cptr arg1 arg2 arg3] applies the C function associated with cptr to (arg1, arg2, arg3).

[app4 cptr arg1 arg2 arg3 arg4] applies the C function associated with cptr to (arg1, arg2, arg3, arg4).

CALLBACK

20

[app5 optr arg1 arg2 arg3 arg4 arg5] applies the C function associated with optr to (arg1, arg2, arg3, arg4, arg5).

CHAR

21

#### Module Char

Char -- SML Basis Library

type char = char

val minChar : char val maxChar : char val maxOrd : int

May raise Chr

raise Chr raise Chr May : int -> char : char -> int : char -> char : char -> char val chr val ord val succ val pred

val >=
val >=
val >=

c : char \* char -> bool
c : char \* char -> bool
> : char \* char -> bool
> : char \* char -> bool
compare : char \* char -> order

[char] is the type of characters.

[minChar] is the least character in the ordering <.

[maxChar] is the greatest character in the ordering <.

[chr i] returns the character whose code is i. Raises Chr if i<0 or i>maxOrd. [maxOrd] is the greatest character code; equals ord(maxChar).

[ord c] returns the code of character c.

[succ c] returns the character immediately following c, or raises thr if c = maxChar.

[pred c] returns the character immediately preceding c, or raises  $\operatorname{Chr}$  if c =  $\min \operatorname{Char}$  .

[isLower c] returns true if c is a lowercase letter (a to z).

[isUpper c] returns true if c is a uppercase letter (A to Z).

[isDigit c] returns true if c is a decimal digit (0 to 9).

CHAR

isAlpha c] returns true if c is a letter (lowercase or uppercase).

[isHexDigit c] returns true if c is a hexadecimal digit (0 to 9 or a to f or A to F).

isAlphaNum c] returns true if c is alphanumeric (a letter or a

isPrint c] returns true if c is a printable character (space or visible) [isSpace c] returns true if c is a whitespace character (blank, newline, cab, vertical tab, new page).

[isGraph c] returns true if c is a graphical character, that is, it is printable and not a whitespace character.

[isPunct c] returns true if c is a punctuation character, that is graphical but not alphanumeric.

ij [isCntrl c] returns true if c is a control character, that is, (isPrint c).

isAscii c] returns true if 0 <= ord c <= 127.

[toLower c] returns the lowercase letter corresponding to c, if c is a letter (a to z or A to Z); otherwise returns c.

toUpper c] returns the uppercase letter corresponding to c, if c is a letter (a to z or A to Z); otherwise returns c. [contains s c] returns true if character c occurs in the string s; false otherwise. The function, when applied to s, builds a table and returns a function which uses table lookup to decide whether a given character is in the string or not. Hence it is relatively expensive to compute val p = contains s but very fast to compute p(c) for any given character.

[notContains s c] returns true if character c does not occur in the string s' false otherwise. Works by construction of a lookup table in the same way as the above function.

[fromString s] attempts to scan a character or ML escape sequence from the string s. Does not skip leading whitespace. For instance, fromString "\\065" equals #"A".

[toString c] returns a string consisting of the character c, if c is printable, alse an ML escape sequence corresponding to c. A printable character is mapped to a one-character string; bell, backspace, tab, newline, vertical tab, form feed, and carriage return are mapped to the two-character strings  $^{\backslash}|_{x}^{n}, ^{-}|_{x}^{n}, ^{$ 

equals "\\^N" equals "\\127" equals "\\128" equals "\\\\" equals "\\\\" 6 8660 toString #"\\" toString #"\"" (chr chr br chr chr toString toString toString coString toString coString coString oString oString coString

[fromCString s] attempts to scan a character or C escape sequence from the string s. Does not skip leading whitespace. For instance, fromString "\\065" equals #"A".

23

[tocString c] returns a string consisting of the character c, if c is printable, else an C escape sequence corresponding to c. A printable character is mapped to a one-character string; bell, backspace, tab, newline, vertical tab, form feed, and carriage texturn are mapped to the two-character strings "\|a", "\|b", octal digits representing the character code. For instance, to String  $\# "A" \equals "A"$ equals "\\\"" equals "\\000" equals "\\000" equals "\\000" equals "A" equals "\\\\" equals equals equals equals equals equals equals equals equals 0 860 ### ु होम् toString #
toString #
toString #
toString # toString toString toString toString toString toString coString coString coString coString toString coString

⊽ " ⊼

[>-] compares character codes. For instance, c1 < c2 returns true if ord(c1) < ord(c2), and similarly for <=, >, >=.

[compare(cl, c2)] returns LESS, EQUAL, or GREATER, according as cl is precedes, equals, or follows c2 in the ordering Char. <

CHARARRAY

### Module CharArray

24

```

```

[vector] is the type of one-dimensional, immutable, zero-based constant-time-access vectors with elements of type Char.char, that is, characters. Type vector admits equality, and vectors v1 and v2 are equal if they have the same length and their elements are equal. The type vector is the same as String.string.

All operations are as for Vector.vector.

26 COMMANDLINE

27

Date -- SML Basis Library

Module Date

DATE

## Module CommandLine

```
CommandLine -- SML Basis Library
val name : unit -> string
val arguments : unit -> string list
```

[name ()] returns the name used to start the current process.

[arguments ()] returns the command line arguments of the current process. Hence List.nth(arguments (), 0) is the first argument.

e.g. 1999 Jan, Feb, ... 1-31 0-23 0-61, permitting leap seconds n time zone west of UTC toString : date -> string fmt : string -> date -> string fromString : string -> date option scan : (char, 'a) StringCvt.reader -> (date, 'a) StringCvt.reader datatype weekday = Mon | Tue | Wed | Thu | Fri | Sat | Sun Jun Dec May Nov date -> int
date -> month
date -> int
date -> Int second : int,
offset : Time.time option
-> date Apr Oct val fromTimeLocal : Time.time -> date val fromTimeUniv : Time.time -> date val toTime : date -> Time.time val localOffset : unit -> Time.time : date \* date -> order Mar Sep : int, : month, datatype month = Jan | Feb | Jul | Aug int, int, day : i hour : i minute : i exception Date val date : { val day
val hour
val minute
val second
val weekDay
val yearDay
val isDst
val offset val compare val toStri val fmt val fromSt type date

These functions convert times to dates and vice versa, and format and scan dates.

[date] is the type of points in time in a given time zone. If the offset is NOWE, then the date is in the local time zone. If the coffset is NOWE, then the offset of the main timezone (ignoring daylight aavings time) west of UTC.

When 0 hours <= t < 12 hours, the represented time is to the west of UTC and the local time is UTC+1.

When 12 hours <= t < 23 hours, the represented time is to the East of UTC and the local time is UTC+2+t).

[date { year, month, day, hour, minute, second, offset } ] returns a canonical date value. Seconds outside the range 0.59 are converted to the equivalent minutes and added to the minutes arrowner to the equivalent minutes and added to the minutes are converted to hours, hours to days, days to months, and months to years. Then the weekday and day number in the year are computed. Leap years are assumed in accordance with the Gregorian calendar, for any year after year 0 A.D.

If the offset is greater than one day  $(24 \ \text{hours})$ , then the excess days are added to the days, and the offset modulo  $24 \ \text{hours}$  is used.

DATE 28

[year dt] returns the year of dt, e.g. 1999.

[month dt] returns the month of dt

[day dt] returns the day of dt

[hour dt] returns the hour of dt.

[minute dt] returns the minute of dt.

[second dt] returns the second of dt.

[weekDay dt] returns the weekday of dt.

[yearDay dt] returns the number of the day in the year of dt. January 1 is day 0, and December 31 is day 364 (and 365 in leap years).

[isDst dt] returns SOME(true) if daylight savings time is in effect at the date dt; returns SOME(false) if not; and returns NONE if this information is unavailable.

[offset dt] returns NONE if the date dt is in the local time zone; returns SOME t where t is the offset west of UTC otherwise. Thus SOME(Time.zeroTime) is UTC.

[compare(dtl, dt2)] returns LESS, EQUAL, or GREATER, according as date dtl precedes, equals, or follows dt2 in time.
Lexicographically compares the dates. Ignores timezone offset and DST. Does not detect invalid dates.

[toString dt] returns a 24 character string representing the date dt

in the following format:

The result may be wrong if the date is not representable as a Time.time value. Raises Date if dt is an invalid date. Corresponds to the ANSI C function 'asctime' [fmt fmtstr dt] formats the date dt according to the format string fluctic. The format string has the same meaning as with the ANSI C function 'striftime'. These ANSI C format codes should work on all platforms:

a abbreviated weekday name (e.g. "Mon")
A full weekday name (e.g. "Monday")
b abbreviated month name (e.g. "Oct")
c date and time (e.g. "Dec 2 06:55:15 1979")
d day of month (01..31)
H hour (00..23)

month number (01..12)
month number (01..12)
minutes (00..59)
minutes (00..59)
minutes (00..59)
minutes (00..51)
minutes (00..51), with Sunday as the first day of week (01.00.00)
meek number (00..53), with Sunday sa the first day of week (01.00.00)
meek number (00..53), with Monday as the first day of week (01.00)
meek number (00..53), with Monday as the first day of week (01.00)
meek number (00..53), with Monday as the first day of week (01.00)

year of century (00..99)

year including century (e.g. 1997) time zone name if it exists; otherwise the empty string the percent character

Example: The current local date in ISO format (e.g. 1998-04-06) can be obtained by using: fmt "%Y-\$m-\$d" (fromTimeLocal (Time.now ()))

[fromString s] scans a 24-character date from the string s, after possible initial whitespace (blanks, tabs, newlines). The format of the string must be as produced by toString. The fields isbst and offset in the resulting date will be NONE. No check of the

consistency of the date (weekday, date in the month,

DATE

53

using the stream accessor getc. Otherwise works as fromString. In case of success, returns SOME(date, rst) where date is the scanned date and rst is the remainder of the stream; otherwise returns [scan getc src] scans a 24-character date from the stream src,

[fromTimeLocal t] returns the local date at (UTC) time t. The resulting date will have offset = NONE. The fields year, month, day, hour, minute, and second are as expected. The resulting isDst may be NONE if the system cannot determine whether daylight savings time is in effect at the given time. Corresponds to the ANSI C function 'localtime'

[fromTimeUniv t] is similar to fromTime, but returns the UTC date at (UTC) time t. The resulting date will have offset = SOME Time.ZeroTime. Corresponds to the ANSI C function 'gmtime'.

[toTime dt] returns the (UTC) time corresponding to the date dt. Uses the isDst time field if it is present (SOME \_) and cannot be calculated from the given date. May raise Date if the given date is invalled. Raises Time.Time if the Date cannot be represented as a Time.time walue. At least the dates in the interval 1970-2030 can be represented as Time.time values. Corresponds to the ANSI C function 'mktime'

UIC. [localOffset ()] is the local time zone offset west of It holds that 0 hours <= localOffset () < 24 hours.

30 DYNARR.

#### Module Dynarray

Dynarray -- polymorphic dynamic arrays a la SML/NJ library

type 'a array

val array : int \* '\_a -> '\_a array
val subarray : '\_a array \* int \* int -> '\_a array
val fromList : '\_a list \* '\_a -> '\_a array
val tabulate : int \* (int -> 'a) \* '\_a -> '\_a array
val sub
val sub
val update : '\_a array \* int -> 'a
val default : 'a array \* int \* '\_a -> unit
val default : 'a array -> 'a
val default : 'a array -> int

['ty array] is the type of one-dimensional, mutable, zero-based unbounded arrays with elements of type 'ty. Type 'ty array does not admit equality.

[array(n, d)] returns a dynamic array, all of whose elements are initialized to the default d. The parameter n is used as a hint of the upper bound on non-default elements. Raises Size if n < 0.

[subArray(a, m, n)] returns a new array with the same default value as a, and whose values in the range [0,n-m] equal the values in a in the range [m,n]. Raises the exception Size if n < m.

[fromList (xs, d)] returns an array whose first elements are those of [xs], and the rest are the default d.

[tabulate(n, f, d)] returns a new array whose first n elements are f 0, f 1, ..., f (n-1), created from left to right, and whose remaining elements are the default d. Raises Size if n < 0.

 $[\operatorname{sub}(a,\ i)\,]$  returns the i'th element of a, counting from 0. Raises Subscript if i < 0.

(update(a, i, x)) destructively replaces the i'th element of a by x. Raises Subscript if i < 0.

default a] returns the default value of the array a.

[bound a] returns an upper bound on the indices of non-default values.

DYNLIB

31

#### Module Dynlib

Dynlib -- dynamic linking with foreign functions

type dlHandle type symHandle exception Closed

datatype flag = RTLD\_LAZY | RTLD\_NOW
val dlopen : { lib : string, flag : flag, global : bool } -> dlHandle
val dlsym : dlHandle -> string -> symHandle
val dlclose : dlHandle -> unit
val ductor : dlHandle -> 'b
val appl : symHandle -> 'b
val appl : symHandle -> 'al -> 'b
val appl : symHandle -> 'al -> 'a2 -> 'a
val appl : symHandle -> 'al -> 'a2 -> 'a
val appl : symHandle -> 'al -> 'a2 -> 'a
val appl : symHandle -> 'al -> 'a2 -> 'a
val appl : symHandle -> 'al -> 'a2 -> 'a
val appl : symHandle -> 'al -> 'a2 -> 'a3 -> 'b

Structure Dynlib provides dynamic loading and calling of C functions, using the dlfcn interface. A dynamic library is a collection of symbols (C variables and functions).

An ML value passed to or returned from a symbol has type 'value' as defined in src/runtime/mlvalues.h. The C functions should use the macroes defined there to access and produce ML values. When writing a C function, remember that the garbage collector may be activated whenever you allocate an ML value. Also, remember that the garbage collector may move values from the young heap to the old one, so that a C pointer pointing into the ML heap may need to be updated. Use the Push\_roots and Pop\_roots macroes to achieve this.

[dlHandle] is the type of dynamic library handles. A dynamic library handle is created by opening a dynamic library using dlopen. This will load the library into the runtime system. The dynamic library handle is used for accessing symbols in that library. The library may be closed and removed from the runtime system using dlclose.

The same library may be opened more than once, resulting in different library handles. The physical library will be loaded only once, though, and will remain in the runtime system until all handles to the library have been closed.

[symHandle] is the type of symbol handles. A symbol handle is used to access a symbol (variable or function) in the dynamic library, using the functions var. appl. app2, ..., app5. Type safety is the responsibility of the programmer; the runtime system performs no type checking. Hence you are advised to add explicit types whenever you define an ML function in terms of var, app1, ..., app5.

To compile xyz.c into xyz.o and then create a dynamic library libxyz.so from xyz.o:

Under Linux and OSF/1 (Digital Unix):
gc~c~o-xyz.o.xyz.o.
ld~shared~o-libxyz.so xyz.o.
under Solaris (ignore the warnings from ld):
gc~c~o-xyz.o.xyz.o.
ld~G-B symbolic~z nodefs -o libxyz.so xyz.o.
Under HP-UX:
ld~c~xyz.o.xyz.o.
ld~b~symbolic~z~o.xyz.o.xyz.o.
ld~b~s~xymbolic~z~o.xyz.o.xyz.o.

If "xyz.o" depends on another library "libabc.a" you may link the required functions into libxyz.so just by adding -labc or libabc.a to the above linker command.

If "xyz.o" depends on another dynamic library "libabc.so" you may specify this by adding -labc to the above linker command. Then Dynlib.dlopen will automatically load libabc.so before libxyz.so.

[dlopen { lib, flag, global } will load and open the library in flee 'lib', returning a handle to it. Libraries are usually specified just by file name, leaving out the directory path. Lihux/Uhix-specific information: Libraries are searched for in heto/la.so.cache. in /usr/lib and /lib. [Note that continued in the Libraries mentioned in the Libraries are searched for in /etc/ld.so.cache is created from /etc/ld.so.coch by running ldconfig; you must be superuser to do that).

If 'global' is true, then the library's global symbols are made available for other libraries subsequently loaded.

[flag] is the type of library loading modes: RTLD\_LAZY and RTLD\_NOW

þe [RTLD\_LAZY] specifies that only symbol relocations will be performed when calling dlopen, whereas function relocations will k performed later when a function is invoked for the first time (if ever). This is the normal situation.

[RTLD NOW] specifies that all function relocations must be performed immediately, also for functions that will never be called. This checks that all functions are defined, but may waste some time. dlsym dlh nam] returns a symbol handle for the symbol called 'nam' in the library associated with dlh. Raises Closed if dlh has been closed. [dlclose dlh] closes the library handle and deallocates the library if there are no more open handles to this library.

The following functions raise Closed if the associated handle has been closed. var sym] returns the value of the C variable associated with sym

appl sym arg1] applies the C function associated with sym to arg1. app2 sym arg1 arg2] applies the C function associated with sym to argl, arg2)

app3 sym arg1 arg2 arg3] applies the C function associated with sym to (argl, arg2, arg3). (app4 sym arg1 arg2 arg3 arg4) applies the C function associated with sym to (arg1, arg2, arg3, arg4).

[app5 sym arg1 arg2 arg3 arg4 arg5] applies the C function associated with sym to (arg1, arg2, arg3, arg4, arg5).

FILESYS

33

#### Module FileSvs

OS.FileSys -- SML Basis Library

type dirstream

openDir : string -> dirstream readdir : dirstream -> string option rewindDir : dirstream -> unit closeDir : dirstream -> unit val openDir

val val

chDir getDir mkDir rmDir isDir

val val val

: string -> unit : unit -> string : string -> unit : string -> unit : string -> bool

: string -> string : string -> string : string -> bool : string -> string realPath fullPath isLink readLink

val val val

: string -> Time.time
: string \* Time.time option -> unit
: string -> unit modTime setTime remove

: {old: string, new: string} -> unit rename val val val

datatype access = A\_READ | A\_WRITE | A\_EXEC val access : string \* access list -> bool

: string -> int val fileSize

: unit -> string val tmpName eqtype file\_id
val fileId
:
val hash
:
val compare :

: string -> file\_id : file\_id -> word : file\_id \* file\_id -> order

They raise OS.SysErr These functions operate on the file system. in case of errors.

[openDir p] opens directory p and returns a directory stream for use by readDir, rewindDir, and closeDir. Subsequent calls to readDir will return the directory entries in some unspecified

[readDir dstr] returns SOME(s), consuming an entry s from the directory stream if it is non-empty; returns NONE if it is empty (When all directory entries have been read). Only entries distinct from the parent arc and the current arc (that is, . and . in Unix, DOS, and Windows; see the Path structure) will be returned.

rewindDir dstr] resets the directory stream as if it had just been

[closeDir dstr] closes the directory stream. All subsequent operations on the stream will raise OS.SysErr.

[chDir p] changes the current working directory to p. This affects calls to the functions use, load, compile in the interactive system, as well as all functions defined in this library. If p specifies a volume name, then this command also changes the current volume (relevant under DOS, Windows, OS/2, etc.).

[getDir ()] returns the name of the current working directory.

[mkDir p] creates directory p on the file system.

[rmDir p] removes directory p from the file system.

34 FILESYS

[isDir p] tests whether p is a directory.

[fullPath p] returns a canonical form of path p, where all occurrences of the arcs "...", "have been expanded or removed, and (under Unix) symbolic links have been fully expanded. Raises SysErr if a directory on the path, or the file or directory named, does not exist or is not accessible, or if there is a link loop.

[realPath p] behaves as fullPath(p) if p is absolute. If p is relative and on the same volume as the current working directory, it returns a canonical path relative to the current working directory, where superfluous occurrences of the arcs ".".".", have been removed, and (under Unix) symbolic links have been fully expanded. Raises SysErr if a directory on the path, or the file or directory named, does not exist or is not accessible, or if there is a link loop. Raises Path if p is relative and on a different volume than the current working directory.

[isLink p] returns true if p names a symbolic link. Raises SysErr if the file does not exist or there is an access violation. On operating systems without symbolic links, it returns false, or raises SysErr if the file does not exist or there is an access violation.

[readLink p] returns the contents of the symbolic link p. Raises SysErr if p does not exist or is not a symbolic link, or there is an access violation. On operating systems without symbolic links, it raises SysErr.

[modTime p] returns the modification time of file p.

[setTime (p, tmopt)] sets the modification and access time of file p. If tmopt is SOME t, then the time t is used; otherwise the current time, that is, Time.now(), is used.

remove p] deletes file p from the file system.

[rename {old, new}] changes the name of file 'old' to 'new'.

[access] is the type of access permissions:

[A\_READ] specifies read access.

[A\_WRITE] specifies write access.

[A\_EXEC] specifies permission to execute the file (or directory).

[access (p, accs)] tests the access permissions of file p, expanding symbolic links as necessary. If the list accs of for required access permission is empty, it tests whether p exists. If accs contains A.READ, A.WRITE, or A.EXEC, respectively, it tests whether the user process has read, write, or execute permission for the file.

the file.

Under Unix, the access test is done with the 'real' user id and group id (as opposed to the 'effective' user id and group id) of the user process. Hence access("file", [A\_RBAD]) may return false, yet the file may be readable by the process, in case the effective user id or group id has been changed by setuid.

[fileSize p] return the size, in bytes, of the file p. Raises SysErr if p does not exist or its directory is not accessible. [tmpName ()] returns a file name suitable for creating a fresh temporary file. Note that there is no guarantee that the file name will be unique, since a file of that name may be created between the call to tmpName and a subsequent call to openOut which creates the file. The file name will be absolute, usually of the form /tmp/xxxxxxxx provided by POSIX tmpnam (3).

[file\_id] is the type of unique identities of file system objects including device ids and volume ids, but possibly insensitive to

FILESYS

35

volume changes on removable volumes, such as tapes and diskettes). The set of file ids is equipped with a total linear order.

[fileId p] returns the file\_id of the file system object named by path p. It holds that fileId pl = fileId p2 if and only if pl and p2 name the same file system object.

[hash fid] returns a hashvalue for fid, suitable for use in a hashtable of file ids (and hence files).

If fidl = fid2 then hash fidl = hash fid2.

If fidl = fid2 then hash fidl = hash fid2.

[compare (fidl, fid2)] returns LESS, EQUAL, or GREATER, according as fidl precedes, equals, or follows fid2 in the total linear order on file ids. This is suitable for e.g. an ordered binary tree of file ids (and hence files).

GDBM

#### **Module Gdbm**

36

Gdbm -- GNU gdbm persistent string hashtables -- requires Dynlib

type table

```
read/write, create if necessary

[table] is the type of an opened table. A value of type table can be used only in the argument f to the withtable function. This makes sure that the table is closed after use.

[opermode] is the type of opening modes. Read-only access (READER) is non-exclusive; read/write access (WRITER, WRCREAT, NEWDB) is exclusive.

[withtable (nam, mod) f] first opens the table db in file nam with mode mod, then applies f to db, then closes db. Makes sure to close db even if an exception is raised during the evaluation of f(db). Raises GdbmError with an informative message in case the table cannot be opened. E.g. the table cannot be opened for writing, and cannot be opened for writing, and cannot be opened for writing if already opened for reading.

A table is only guaranteed to work properly if created by withtable using open modes WRCREAT or NEWDB. If you create a table by creating and then opening an empty file, then numitems, listKeys, listItems, etc. will raise an exception.

withtables nammod f], where nammod = [(nam1, mod1), ..., (namn, modn)], withtable (nam1, mod1) (fn db1 =>
withtable (nam2, mod2) (fn db2 => is equivalent to

That is, first opens the databases dbl, db2, ... in that order in files naml, nam2, ... with modes mod1, mod2, ..., then applies f to [db1, db2, ...], and finally closes [db1, db2, ...]. Makes sure to close all databases even if an exception is raised during the opening of db1, db2, ... or during the evaluation of f[db1, db2, ...].

[add db (k,v)] adds the pair (k,v) to db. Raises AlreadyThere if there is a pair  $(k,\_)$  in db already. Raises NotWriter if db is not opened in write mode. GDBM

37

pair insert db  $(k,\ v)$  adds the pair  $(k,\ v)$  to db, replacing any  $E(k,\ \_)$  at k if present. Raises NotWriter if db is not opened

write mode.

find db k] returns v if the pair (k, v) is in db; otherwise raises NotFound peek db k] returns SOME v if the pair (k, v) is in db; otherwise returns NONE.

hasKey db k] returns true if there is a pair (k, \_) in db; otherwise returns false. [remove db k] deletes the pair  $(k, \ \ \ )$  from the table if present; otherwise raises NotFound. Raises NotWriter if db is not opened write mode.

[listKeys db] returns a list of all keys in db in an unspecified

[numItems db] is the number of (key, value) pairs in db. Equivalent to length(listKeys db).

[listItems db] returns a list of all (key, value) pairs in db in some

order. Equivalent to List.map (fn key => (key, find(db,key))) (listKeys db)

[app f db] is equivalent to List.app f (listItems db), provided the function f does not change the set of keys in the table.
Otherwise the effect is unpredictable.

[map f db] is equivalent to List.map f (listItems db), provided the function f does not change the set of keys in the table.
Otherwise the result and effect are unpredictable.

[fold f a db] is equivalent to List.foldr (in ((k, v), r) => f(k, v, r)) a (list.tems db) provided the function f does not change the set of keys in the table. Otherwise the result and effect are unpredictable.

[fastwrite] can be set to speed up writes to a table. By default, ifsatwrite is false and every write to a table will be followed by file system synchronization. This is safe, but slow if you perform thousands of writes. However, if !fastwrite is true when calling withtable, then writes may not be followed by synchronization, which may speed up writes considerably. In any case, the file system is synchronized before withtable returns.

reorganize db] has no visible effect, but may be called after a lot of deletions to shrink the size of the table file.

This is an interface to version 1.7.3 of Thomas Boutell's gd image package for creating PNG images.

39

[image] is the type of images being drawn. They can be created from scratch, imported from PNG files, and exported to PNG files.

All functions correctly clip to the actual size of the image.

[color] is the type of colors. Currently there can be at most 256 different colors in an image.

[style] is the type of drawing styles. A style is either a color, or transparent.

[mode] is the type of drawing modes for line drawing and filling. It may be one of where c is a color Transparent

Styled stys for line drawing using the given image as brush Styled stys in the given vector to create a dashed line StyledBrushed (vis, img) for line drawing, using the given image as a brush, cyclically switching it on and off according to the given bool vector

for filling, using the given image as a tile Tiled img

[font] is the type of fonts: Tiny, Small, MediumBold, Large, Giant

[rgb] is the type of (x, g, b) triples, where the components indicate color intensity as an integer value in the range 0..255.

[xy] is the type of pairs, used for (x, y) coordinates and to indicate dimensions (width, height). The origin (0, 0) is the upper left-hand corner of the image. The x coordinates increase the right; the y coordinates increase downwards.

h) and be [image (w, h) rgb] creates a new empty image with size  $(w, the\ background\ color\ rgb.$  Raises Fail if the image cannot

fromPng filename] reads an image from the given PNG file. Raises Fail if the file does not exist or does not contain a PNG image. size img] returns (w, h) where w is the width and h the height of

toPng img filename] write the image to the given file in PNG

[stdoutPng img] writes the image to standard output in PNG format, preceded by the HTTP header "Content-type: image/png/n\n". Useful in CGI scripts. [color img rgb] returns the color code corresponding to rgb in the color table of img. Reuses the color code if it has already been allocated; otherwise allocates the color if possible; otherwise returns an approximation to the color rgb. [htmlcolors im] returns a record containing the 16 standard HTML colors: aqua, black, blue, fuchsia, gray, green, lime, marcon, navy, olive, purple, red, silver, teal, white, yellow. This call will allocate all these colors in the color table of the image, even if you do not use all of them. [rgb img color] returns (r, g, b) where r, g, b are the component intensities of the given color in the color table of img.

[getTransparent img] returns SOME c where c is the 'transparent' color of the image, if any; otherwise returns NONE.

[setTransparent img col] makes the given color transparent in the

image.

[noTransparent img] makes all colors non-transparent in the image. This is useful for images that are to be used as tiles for filling. Such images are not allowed to have a transparent color.

drawPixel img mode xy] draws the pixel in img at xy using

(drawLine img mode (xy1, xy2)] draws a line in img from xy1 to xy2 using the given mode

[drawRect img mode (xy1, xy2)] draws a rectangle in img with opposing corners xy1 and xy2 using the given mode.

[fillRect img mode (xy1, xy2)] draws a filled rectangle in img with opposing corners xy1 and xy2 using the given mode.

[drawPolygon img mode xys] draws a polygon in img with corners as given by the vector xys of coordinates using the given mode. [fillPolygon img mode xys] draws a filled polygon in img with corners as given by the vector xys of coordinates using the given

[drawArc img mode  $\{$  c, wh, from, to  $\}$ ] draw part of an ellipsis arc in img, with center c, width and height wh, using the given 'from' and 'to' angles, given in degrees (0..360).

[fill img mode xy] fills the region in img around xy which has the same color as the point at img, using the given mode.

[fillBorder img mode xy col] fills the region in img around xy which is delimited by the color col, using the given mode.

[copy { src, srcxy, srcwh, dst, dstxy }] copies part of the image src into the image dst, without rescaling. More precisely, copies the subimage of src whose upper left-hand corner is srcxy and whose size is srcwh, into the subimage of dst whose upper left-hand corner is dstxy. The images for and dst may be the same, but if the subimages overlap, then the result is unpredictable.

[copyResize { src, srcxy, srcwh, dst, dstxy, dstwh }] copies part of the image src into the image dst, rescaling to the given size dstwh of the destination subimage. Otherwise works as copy.

[char img col font xy ch] draws the character ch left-right (to be read from south) in img at xy using the given color. charUp img col font xy ch] draws the character ch bottom-up (to

read from east) in img at xy using the given color.

[string img col font xy s] draws the string s left-right (to be read from south) in img at xy using the given color.

[stringUp img col font xy s] draws the string s bottom-up (to be read from east) in img at xy using the given color.

[charsize font] returns (w, h) where w is the width and h the height, in pixels, of each character in the given font.

43

[Bind] is the exception raised when the right-hand side value in valbind does not match the left-hand side pattern.

Chr] signals an attempt to produce an unrepresentable character.

Div] signals an attempt to divide by zero.

[Domain] signals an attempt to apply a function outside its domain of definition; such as computing Math.sqrt( $\sim 1$ ).

[Fail] signals the failure of some function, usually in the Moscow ML specific library structures.

[Match] signals the failure to match a value against the patterns in a case, handle, or function application.

Overflow] signals the attempt to compute an unrepresentable number

[Subscript] signals the attempt to use an illegal index in an array, dynarray, list, string, substring, vector or weak array.

[Size] signals the attempt to create an array, string or vector that is too large for the implementation.

Graphic] signals the failure of Graphics primitives (DOS only).

Interrupt] signals user interrupt of the computation

[Invalid\_argument] signals the failure of a function in the runtime

[Io { function, name, cause }] signals the failure of an input/output operation (function) when operating on a file (name). The third field (cause) may give a reason for the failure.

[Out\_of\_memory] signals an attempt to create a data structure too large for the implementation, or the failure to extend the heap or stack.

[SysErr (msg, err)] signals a system error, described by msg. A system error code may be given by err. If so, it will usually hold that msg = OS.errorMsg err.

SML Basis Library values

[! rf] returns the value pointed to by reference rf.

 $[:=(rf,\,e)]$  evaluates rf and e, then makes the reference rf point to the value of e. Since := has infix status, this is usually written

[o(f, g)] computes the functional composition of f and g, that is, fn x => f(g x). Since o has infix status, this is usually written f o g

[ignore e] evaluates e, discards its value, and returns () : unit.

[before(e1, e2)] evaluates e1, then evaluates e2, then returns the value of e1. Since before has infix status, this is usually written value of el. Sinc el before e2

ij [exnName exn] returns a name for the exception constructor in exn. Never raises an exception itself. The name returned may be that cany exception constructor aliasing with exn. For instance, let exception E1: exception E2 = E1 in exnName E2 end may evaluate to "E1" or "E2".

to [exnMessage exn] formats and returns a message corresponding

['a frag] is the type of quotation fragments, resulting from the

('a ref] is the type of mutable references to values of type 'a.

exception exn. For the exceptions defined in the SML Basis Library, the message will include the argument carried by the exception.

Moscow ML top-level values Additional not b] returns the logical negation of b.

[^] is the string concatenation operator.

[=] is the polymorphic equality predicate.

[<>] is the polymorphic inequality predicate

ceil r] is the smallest integer >= r (rounds towards plus infinity). May raise Overflow.

[floor r] is the largest integer <= r (rounds towards minus infinity) May raise Overflow.

real i] is the floating-point number representing integer Equivalent to Real.fromInt [round r] is the integer nearest to r, using the default rounding mode. May raise Overflow.

[trunc r] is the numerically largest integer between r and rounds towards zero). May raise Overflow

vector [x1, ..., xn]] returns the vector #[x1, ..., xn]

[ < (x1, x2) ] [ <=(x1, x2) ] [ > (x1, x2) ] [ > (x1, x2) ] [ > (x1, x2) ]

These are the standard comparison operators for arguments of type int, Word.word, Word8.word, real, char or string. [makestring v] returns a representation of value v as a string, for v of type int, Word.word, Word8.word, real, char or string.

May  $\sim x$ ] is the numeric negation of x (which can be real or int). raise Overflow [abs x] is the absolute value of x (which can be real or int). May raise Overflow.

[+ (e1, e2)] [- (e1, e2)] [\* (e1, e2)]

These are the standard arithmetic operations for arguments of type int, Word.word, Word8 word, and real. They are unsigned in the case of Word.word and Word8.word. May raise Overflow.

e2. [/ (el, e2)] is the floating-point result of dividing el by May raise Div and Overflow. [div(el, e2)] is the integral quotient of dividing el by e2 for arguments of type int, Word word, and Word8 word. See Int.div and Word.div for more details. May raise Div, Overflow.

[mod(e1, e2)] is the remainder when dividing e1 by e2, for arguments of type int, Word.word, and Word8.word. See Int.mod and Word.mod for more details. May raise Div.

HELP

#### Module Help

help functions Help -- on-line : string -> unit

val help

: int ref
: string list ref
: string list ref
: {term : string, file : string, list ref val displayLines val helpdirs

val helpdirs
val indexfiles
val specialfiles
val become
val browser
val defaultBrowser

string vector ref (string -> unit) ref string -> unit

[help s] provides on-line help on the topic indicated by string

help "lib"; gives an overview of the Moscow ML library. help "id"; provides help on identifier id (case-insensitive).

If exactly one identifier in the library matches id (case-insensitive), then the browser opens the signature defining that identifier, positioning the first occurrence of id at the center of the screen.

If more than one identifier matches id (case-insensitive), then a small menu lists the signatures containing the identifier. To invoke the browser, just type in the number of the desired signature. The browser accepts the following commands, which must be followed by a newline:

ರಶ

move down by half a screen move up by half a screen move to top of file move to bottom of file cyclically search for string str in help file (case-insensitive) search for next occurrence of str /str d p

quit the browser

A newline by itself moves down one screen (24 lines).

þe t t [helpdirs] is a reference to a list of additional directories to searched for help files. The directories are searched in order, after the -stdlib directory.

[indexfiles] is a reference to a list of full paths of help term index files. Setting 'indexfiles' affects subsequent invocations of 'help'. (Every invocation of 'help' reads the index files anew).

[specialfiles] is a reference to a list of {term, file, title} records, each of which maps a search term to the specified file with the specified title (in the browser). The string in the 'term' field should be all lowercase, since the argument passed to help' will be converted to lowercase. (welcome] is a reference to the text shown in response to the query nelp "". This is a vector of lines of text. help "".

[browser] is a reference to the function that gets invoked on the text of the help file. Initially set to defaultBrowser.

defaultBrowser] is the default (built-in) help browser.

[displayLines] is a reference to the size of the display (window) assumed by the defaultBrowser; initially 24 lines. Set it to the actual size of your window for best results.

: StringCvt.radix
-> (char, 'a) StringCvt.reader -> (int, 'a) StringCvt.reader
: StringCvt.radix -> int -> string : int -> int : int -> int : int -> int : int -> int toLarge fromLarge toInt fromInt val scan val fmt val val

Overflow val toString : int -> string val fromString : string -> int option [precision] is SOME n, where n is the number of significant bits in an integer. In Moscow ML n is 31 in 32-bit architectures and 63 in 64-bit architectures. integer.

[minInt] is SOME n, where n is the most negative integer.

[maxInt] is SOME n, where n is the most positive integer.

 $[\sim]$   $[\ast]$   $[\ast]$   $[\ast]$  are the usual operations on integers. They raise Overflow if the result is not representable as an integer.

[abs] returns the absolute value of its argument. Raises Overflow if applied to the most negative integer.

[mod] is the remainder for div. If q=i div d and r=i mod d then it holds that qd+r=i, where either 0 <= r < d or d < r <= 0. Evaluating i mod 0 raises Div, whereas i mod  $\sim 1=0$ , for all i. [div] is integer division, rounding towards minus infinity. Evaluating i div 0 raises Div. Evaluating i div ~1 raises Overflow if i is the most negative integer.

[quot] is integer division, rounding towards zero. Evaluating quot(i, 0) raises Div. Evaluating quot(i,  $\sim$ 1) raises Overflow if is the most negative integer.

INT

47

[rem(i, d)] is the remainder for quot. That is, if q = quot(i, d) and r = rem(i, d) then d \* q + r = i, where r is zero or has the same sign as i. If made infix, the recommended fixity for quot and

infix 7 quot

[min(x, y)] is the smaller of x and

 $[\max(x, y)]$  is the larger of x and y.

[sign x] is  $\sim 1$ , 0, or 1, according as x is negative, zero, or positive.

\[ \]

[>=] are the usual comparisons on integers.

[compare(x, y)] returns LESS, EQUAL, or GREATER, according as x is less than, equal to, or greater than y.

[sameSign(x, y)] is true iff sign x = sign y.

toInt x] is x (because this is the default int type in Moscow ML).

[fromInt x] is x (because this is the default int type in Moscow ML).

[toLarge x] is x (because this is the largest int type in Moscow ML).

from Large x] is x (because this is the largest int type in Moscow ML)

[fmt radix i] returns a string representing i, in the radix (base) specified by radix.

output format	 ~?[01]+	~?[0-7]+	~5[0-0]+	~?[0-9A-F]+
	 2)	8	10)	16)
	 (base	(base	(base	(base
tion	 binary	octal	decimal	hexadecimal
descript	 signed	signed	signed	signed
radix	 BIN	OCT	DEC	HEX

[toString i] returns a string representing i in signed decimal format. Equivalent to (fmt DEC i).

[fromString s] returns SOWE(i) if a decimal integer numeral can be scanned from a prefix of string s, ignoring any initial whitespace; returns NOME otherwise. A decimal integer numeral must have form, after possible initial whitespace:

[scan radix getc charsrc] attempts to scan an integer numeral from the character source charsrc, using the accessor getc, and ignoring any initial whitespace. The radix argument specifies the base of the numeral (BIN, OCT, DEC, HEX). If successful, it returns SOME(i, rest) where i is the value of the number scanned, and rest is the unused part of the character source. A numeral must have form, after possible initial whitespace:

[+~-]?[0-1]+ [+~-]?[0-7]+ [+~-]?[0-9]+ [+~-]?[0-9a-fA-F]+ input format radix BIN

[intset] is the type of sets of integers.

empty] is the empty set of integers.

[singleton i] is the singleton set containing i.

[add(s, i)] adds item i to set s.

set s. [addList(s, xs)] adds all items from the list xs to the

[isEmpty s] returns true if and only if the set is empty.

equal(s1, s2)] returns true if and only if the two sets have same elements. s2. Jo [isSubset(s1, s2)] returns true if and only if s1 is a subset

[member(s, i)] returns true if and only if i is in s.

delete(s, i)] removes item i from s. Raises NotFound if i is not in

[numItems s] returns the number of items in set s.

union(s1, s2)] returns the union of s1 and s2.

intersection(s1, s2)] returns the intersection of s1 and s2

[difference(s1, s2)] returns the difference between s1 and s2 (that is, the set of elements in s1 but not in s2).

[listItems s] returns a list of the items in set s, in increasing

app f s] applies function f to the elements of s,

revapp f s] applies function f to the elements of s, in decreasing

[fold] f e s] applies the folding function f to the entries of the set in increasing order.

[foldr f e s] applies the folding function f to the entries of the set in decreasing order.

[find  $p\ s$ ] returns SOWE i, where i is an item in s which satisfies p, if one exists; otherwise returns NONE.

51

#### Module Lexing

Lexing -- run-time library for lexers generated by mosmllex Closely based on the library for camllex. Copyright 1993 INRIA, France

local open Obj in

type lexbuf

val createLexerString : string -> lexbuf
val createLexer : (CharArray.array -> int -> int) -> lexbuf

: lexbuf -> string : lexbuf -> int -> char : lexbuf -> int : lexbuf -> int getLexeme

getLexemeChar getLexemeStart getLexemeEnd val val

For internal use in generated lexers:

: lexbuf -> obj : lexbuf -> 'a : lexbuf -> char = 1 "get\_next\_char" val backtrack prim\_val getNextChar val dummyAction val backtrack

= 1 "field1" = 1 "field2" = 1 "field4" = 1 "field4" = 1 "field6" : lexbuf -> string = : lexbuf -> int : lexbuf -> int = : nn : lexbuf -> (lexbuf -> obj) = : nn : lexbuf -> (lexbuf -> obj) = : nn : lexbuf -> (lexbuf -> obj) = : nn : lexbuf -> obj) prim\_val getLexbuffer : le prim\_val getLexbsPos : le prim\_val getLexCurrPos : le prim\_val getLexCurrPos : le prim\_val getLexCurrPos : le prim\_val getLexLastPos : le

examples, see mosml/examples/lexyacc and mosml/examples/calc. These functions are for use in mosmllex-generated lexers. further information, see the Moscow ML Owner's Manual. Fo

[lexbuf] is the type of lexer buffers. A lexer buffer is the argument passed to the scanning functions defined by the mosmllex-generated scanners. The lexer buffer holds the current state of the scanner, plus a function to refill the buffer from the

[createLexerString s] returns a lexer buffer which reads from the given string s. Reading starts from the first character in the string. An end-of-input condition is generated when the end of the string is reached.

[createLexer f] returns a lexer buffer that will use the given function f for reading additional input. When the lexer needs more characters, it will call the given function as (f carr n), where carr is a character array, and n is an integer. The function should put at most characters or in carr, starting at character number 0, and return the number of characters actually stored. A return value of 0 means end of input.

A lexer definition (input to mosmllex) consists of fragments of this form

rhs1 rhs2 rhs3 lhs1 lhs2 lhs3

parse

where the lhs are regular expressions matching some string of

52 LEXING

characters, and the rhs are corresponding semantic actions, written in ML. The following functions can be used in the semantic actions:

[getLexeme lexbuf] returns the string matched by the left-hand side regular expression.

[getLexemeChar lexbuf i] returns character number i in the matched string.

[getLexemeStart lexbuf] returns the start position of the matched string (in the input stream). The first character in the stream has position 0.

[getLexemeEnd lexbuf] returns the end position, plus one, of the matched string (in the input stream). The first character in the stream has position 0.

LIST

#### Module List

Subscript Subscript Subscript : ('a -> bool) -> 'a list -> 'a option : ('a -> bool) -> 'a list -> 'a list : ('a -> bool) -> 'a list -> ('a list \* 'a list) Empty Empty Empty Size : ('a -> unit) -> 'a list -> unit : ('a -> 'b) -> 'a list -> 'b list : ('a -> 'b option) -> 'a list -> 'b list م م : ('a \* 'b -> 'b) -> 'b -> 'a list -> : ('a \* 'b -> 'b) -> 'b -> 'a list -> : 'a list -> ('a \* 'a list) option : ('a -> bool) -> 'a list -> bool : ('a -> bool) -> 'a list -> bool : 'a list \* 'a list -> 'a list : 'a list list -> 'a list : 'a list \* 'a list -> 'a list : int \* (int -> 'a) -> 'a list : 'a list \* int -> 'a : 'a list \* int -> 'a list : 'a list \* int -> 'a list : 'a list -> bool : 'a list -> 'a : 'a list -> 'a list : 'a list -> 'a : 'a list -> 'a list : 'a list -> int List -- SML Basis Library datatype list = datatype list exception Empty val app val map val mapPartial : val @ val concat val revAppend val find val filter val partition val tabulate val exists val all val getItem val length foldr foldl val null val hd val tl val last val nth val take val drop val rev val val

['a list] is the type of lists of elements of type 'a.

[null xs] is true iff xs is nil.

[hd xs] returns the first element of xs. Raises Empty if xs is nil.

[tl xs] returns all but the first element of xs.

Raises Empty if xs is nil.

[last xs] returns the last element of xs. Raises Empty if xs is nil.

[th(xs, i)] returns the i'th element of xs, counting from 0.

Raises Subscript if i.0 or i>=length xs.

[take(xs, i)] returns the first i elements of xs. Raises Subscript if i.0 or i>=north xs.

[take(xs, i)] returns what is left after dropping the first i elements of xs. Raises Subscript if i.0 or i>=north xs.

It holds that take(xs, i) @ drop(xs, i) = xs when 0 <= i <= length xs.

It holds that take(xs, i) @ drop(xs, i) = xs when 0 <= i <= length xs.

[rev xs] returns the list of xs's elements, reversed.
[xs @ ys] returns the list which is the concatenation of xs and ys.
[concat xss] returns the list which is the concatenation of all the

[length xs] returns the number of elements in xs.

LIST 5

lists in xss.

revAppend(xs, ys)] is equivalent to rev xs @ ys, but more efficient.

[app f xs] applies f to the elements of xs, from left to right

[map f xs] applies f to each element x of xs, from left right, and returns the list of f's results.

from left [mapPartial f xs] applies f to each element x of xs, from to right, and returns the list of those y's for which f(x) evaluated to SOME y. [find p xs] applies f to each element x of xs, from left to right until p(x) evaluates to true; returns SOME x if such an x exists otherwise NONE.

[filter p xs] applies p to each element x of xs, from left to right, and returns the sublist of those x for which p(x) evaluated to true. [partition p xs] applies p to each element x of xs, from left to right, and returns a pair (pos, neg) where pos is the sublist of those x for which p(x) evaluated to true, and neg is the sublist of those for which p(x) evaluated to false.

[foldr ops e xs] evaluates x1 % (x2 % ( ... % (x(n-1) % (xn % e)) ... )) where xs = [x1, x2, ..., x(n-1), xn], and % is taken to be infixed.

[foldl ops e xs] evaluates xn \$ (x(n-1) \$ ( ... \$ (x2 \$ (x1 \$ e)))) where xs = [x1, x2, ..., x(n-1), xn], and \$ is taken to be infixed.

[exists p xs] applies p to each element x of xs, from left to right until p(x) evaluates to true; returns true if such an x exists, otherwise false.

[all p xs] applies p to each element x of xs, from left to right until p(x) evaluates to false; returns false if such an x exists, otherwise true. [tabulate(n, f)] returns a list of length n whose elements are f(0), f(1), ..., f(n-1), created from left to right. Raises Size if n<0.

[getItem xs] attempts to extract an element from the list xs. It returns NONE if xs is empty, and returns SOME (x, xr) if xs=x::xr. This can be used for scanning booleans, integers, reals, and so on from a list of characters. For instance, to scan a decimal integer from a list cs of characters, compute Int.scan StringCvt.DEC List.getItem cs

LISTPAIR

55

#### **Module ListPair**

ListPair -- SML Basis Library

ຸບຸບ val zip : 'a list \* 'b list -> ('a \* 'b) list
val unzip : ('a \* 'b) list -> 'a list \* 'b list
val map : ('a \* 'b -> 'c) -> 'a list \* 'b list -> 'c list
val app : ('a \* 'b -> unit) -> 'a list \* 'b list -> unit
val all : ('a \* 'b -> bool) -> 'a list \* 'b list -> bool
val exists : ('a \* 'b -> bool) -> 'a list \* 'b list -> bool
val foldr : ('a \* 'b \* 'c -> 'c) -> 'c -> 'a list \* 'b list -> val foldl : ('a \* 'b \* 'c -> 'c) -> 'c -> 'a list \* 'b list -> 'a list + 'b list -> 'a l

These functions process pairs of lists. No exception is raised when the lists are found to be of unequal length. Instead the excess elements from the longer list are disregarded.

 $[\text{tip }(xs,\ ys)]$  returns the list of pairs of corresponding elements from xs and ys.

[unzip xys] returns a pair (xs, ys), where xs is the list of first components of xys, and ys is the list of second components from xys. Hence zip (unzip xys) has the same result and effect as xys.

[map f (xs, ys)] applies function f to the pairs of corresponding elements of xs and ys and returns the list of results. Hence map f (xs, ys) has the same result and effect as List.map f (zip (xs, ys)).

[app f (xs, ys)] applies function f to the pairs of corresponding elements of xs and ys and returns (). Hence app f (xs, ys) has the same result and effect as List.app f (zip (xs, ys)).

[all p (xs, ys)] applies predicate p to the pairs of corresponding elements of xs and ys until p evaluates to false or one or both lists is exhausted; returns true if p is true of all such pairs; otherwise false. Hence all p (xs, ys) has the same result and effect as Lisp.all p (zip (xs, ys)).

[exists p (xs, ys)] applies predicate p to the pairs of corresponding elements of xs and ys until p evaluates to true or one or both lists is exhausted; returns true if p is true of any such pair; otherwise false. Hence exists p (xs, ys) has the same result and effect as Lisp.exists p (zip (xs, ys)).

[foldr f e (xs, ys)] evaluates f(x1, y1, f(x2, y2, f(..., f(xn, yn, e)))) where xs = [x1, x2, ..., x(n-1), xn, ...], ys = [y1, y2, ..., y(n-1), yn, ...], and n = min(length xs, length ys). Equivalent to List.foldr (fn ((x, y), r) => f(x, y, r)) e (zip(xs, ys)).

[fold] f e (xs, ys)] evaluates f(xn, yn, f( ..., f(x2, y2, f(x1, y1, e)))) where xs = [x1, x2, ..., x(n-1), xn, ...], ys = [y1, y2, ..., x(n-1), yn, ...], and ys = [y1, x2, ..., x(n-1), yn, ...], and [y = [n] (length xs, length ys).

Equivalent to List fold1 (fn  $((x, y), r) \Rightarrow f(x, y, r)$ ) e (zip(xs, ys)).

#### Module Listsort

Listsort

sort : ('a \* 'a -> order) -> 'a list -> 'a list
sorted : ('a \* 'a -> order) -> 'a list -> bool val sort [sort ordr xs] sorts the list xs in nondecreasing order, using the given ordering. Uses Richard O'Keefe's smooth applicative merge

[sorted ordr  $\kappa s$ ] checks that the list  $\kappa s$  is sorted in nondecreasing order, in the given ordering.

LOCATION

57

#### Module Location

Location -- error reporting for mosmllex and mosmlyac Based on src/compiler/location from the Caml Light 0.6 distribution

Source file positions Position of the first character Position of the character following the last datatype Location = Loc of int

val errLocation : string \* BasicIO.instream \* Lexing.lexbuf -> Location : string \* BasicIO.instream \* Lexing.lexbuf -> Location -> unit val errMsg

errPrompt : string -> 'a enrlocation : Location val errProm
val nilLoca
val getCurr
val mkLoc
val xLR
val xL
val xKL
val xKR
val xXRR
val xXRR

getCurrentLocation: unit -> Location
mkLoc: 'a -> Location \* 'a
xLR: Location \* 'a -> Location
xL : Location \* 'a -> int
xR : Location \* 'a -> int
xXR : Location \* 'a -> int
xXR: Location \* 'a -> Location
xXRI: Location \* 'a -> Location
xXRI: Location \* 'a -> Location

These functions support error reporting in lexers and parsers generated with mosmllex and mosmlyac. The directory mosml/examples/lexyacc/ contains an example of their use.

[errLocation (file, stream, lexbuf) loc] prints the part of the lexer input which is indicated by location loc.

ij If file <> "" then it is assumed to be the name of the file from which the lexer reads, the stream is assumed to be an open input stream associated with this file, and lexbuf is the lexer buffer used to read from the stream. Under MS DOS (and presumably Windows, OS/2, and MacOS), the stream must have been opened in binary mode (with Nonstdio.open\_in\_bin), or else the positioning the file will be wrong (due to the translation of CRLF into newline in text files).

If file = "" then the lexer is assumed to read from some source other than a stream, and the lexbuf (rather than the instream) is used to obtain the location indicated, if possible. In this case the stream is immaterial; it will not be used.

[errMsg (file, stream, lexbuf) loc msg] calls errLocation to print the indicated part of the lexer input, then prints the error message msg and raises exception Fail.

o [errPrompt msg] prints "! ", the string msg, and a newline standard output.

[nilLocation] is the undefined location.

[getCurrentLocation ()] can be called within the semantic action part of a grammar rule (only) and returns the location of the string matching the left-hand side of the rule.

[mkLoc a] can be called within the semantic action part of a grammar rule (only), and returns a pair (loc, a) of the current location and the value a. This is typically used to decorate abstract syntax tree nodes with location information, for use in subsequent error reports.

xLR loc\_a] returns the location of the decorated value loc\_a.

[xL loc\_a] returns the left end position of loc\_a.

xR loc\_a] returns the right end position of loc\_a.

[xxIR loc\_a loc\_b] returns the location extending from the left end of loc\_a to the right end of loc\_b.

LOCATION

28

[xxRL loc\_a loc\_b] returns the location extending from the right end of loc\_a to the left end of loc\_b.

#### Module Math

Math -- SML Basis Library

type real = real

: real e bj. val val

sgrt sin cos tan atan asin acos

: real -> real 0 : real -> real val val val val val val

exp pow ln log10 sinh cosh tanh

[e] is the base of the natural logarithm: 2.7182818284590452354.

[pi] is the circumference of the circle with diameter 1, that is, 3.14159265358979323846.

[sqrt x] is the square root of x. Raises Domain if x < 0.0.

[sin r] is the sine of r, where r is in radians.

[cos r] is the cosine of r, where r is in radians.

[tan r] is the tangent of r, where r is in radians. Raises Domain if r is a multiple of pi/2.

[atan t] is the arc tangent of t, in the open interval ]  ${\rm \sim}pi/2,~pi/2$  [.

[asin t] is the arc sine of t, in the closed interval [  $\mbox{-pi/2},\mbox{ pi/2}$  ]. Raises Domain if abs x > 1.

[acos t] is the arc cosine of t, in the closed interval [ 0, pi ]. Raises Domain if abs  $x\,>\,1.$ 

[atan2(y, x)] is the arc tangent of y/x, in the interval  $1 \sim pi$ , pi], except that atan2(y, 0) = sign y \* pi/2. The quadrant of the result list the same as the quadrant of the point (x, y). Hence sign(cos(atan2(y, x))) = sign x and sign(sin(atan2(y, x))) = sign y.

[exp x] is e to the x'th power.

[pow (x, y)] is x it the y'th power, defined when y >= 0 and (y integral or x >= 0) or y < 0 and (y integral and x <> 0.0) or x >= 0.

We define pow(0, 0) = 1.

[In x] is the natural logarithm of x (that is, with base e). Raises Domain if x <= 0.0.

[log10 x] is the base-10 logarithm of x. Raises Domain if x <= 0.0.

[sinh x] returns the hyperbolic sine of x, mathematically defined (exp x - exp  $(\hbox{-x}))$  / 2. Raises Overflow if x is too large.

as

[cosh x] returns the hyperbolic cosine of x, mathematically defined as (exp x + exp (-x)) / 2. Raises Overflow if x is too large.

MATH 9

[tanh x] returns the hyperbolic tangent of x, mathematically defined as (sinh x) / (cosh x). Raises Domain if x is too large.

val val val	val val	val val val	val val val	val val	val

These values and functions are available in the Moscow ML interactive system only.

: unit -> 'a

quit

val

[printVal e] prints the value of expression e to standard output exactly as it would be printed at top-level, and returns the value of e. Output is flushed immediately. This function is provided as a simple debugging aid. The effect of printVal is similar to that of 'print' in Edinburgh ML or Umeaa ML. For string arguments, the effect of SML/W print can be achieved by the function Textlo.print : string -> unit.

[printDepth] determines the depth (in terms of nested constructors, records, tuples, lists, and vectors) to which values are printed by the top-level value printer and the function printVal. The components of the value whose depth is greater than printDepth are printed as '#'. The initial value of printDepth is 20. This value can be changed at any moment, by evaluating, for example, printDepth := 17:

[printLength] determines the way in which list values are printed by the top-level value printer and the function printVal. If the length of a list is greater than printLength, then only the first printLength elements are printed, and the remaining elements are printed as v..... The initial value of printLength is 200. This value can be changed at any moment, by evaluating, for example, printLength := 500;

[quit ()] quits Moscow ML immediately.

[installPP pp] installs the prettyprinter pp : ppstream -> ty -> unit at type ty. The type ty must be annihary (parameter-less) type constructor representing a datatype, either built-in (such as bool) or user-defined. Whenever a value of type ty is about to be printed by the interactive system, or function printval is invoked on an argument of type ty, the pretty-printer pp will be invoked to print it. See library unit PP for more information.

[use "f"] causes ML declarations to be read from file f as if they were entered from the console. A file loaded by use may, in turn, evaluate calls to use. For best results, use 'use' only at top

level, or at top level within a use'd file.

accept (without warnings) all extensions to the SML Modules language. The extensions are: higher-order modules (functors defined within structures and functors); first-order modules structures can be packed as values, and values can be unpacked as structures); and recursively defined modules (signatures and structures). The liberal, conservative, and orthodox modes affect the functions compile, compilestructure, and compileroplevel. The liberal indea may be set also by the mosml option -liberal. liberal ()] sets liberal mode for the compilation functions:

unctions: accept all extensions to the SML Modules language, but The conservative mode may be set ervative. This is the default. conservative ()] sets conservative mode for the compilation -conservative. issue a warning for each use. also by the mosml option -conse

SML Modules language. The orthodox mode may be compilation functions: [orthodox ()] sets orthodox mode for the reject all uses of the extensions to the That is, accept only SML Modules syntax. set also by the mosml option -orthodox. compile "U.sig"] will compile and elaborate the specifications in ij. file U.sig in structure mode, producing a compiled signature U in file U.ui. This function is backwards compatible with Moscow ML 1.44 and earlier. Equivalent to compileStructure [] "U.sig". [compile "U.sml"] will elaborate and compile the declarations in file U.sml in structure mode, producing a compiled structure U in bytecode file U.o. If there is an explicit signature file U.sig, then file U.ui must exist, and the unit body must match the signature. If there is no U.sig, then an inferred signature file U.ui will be produced also. No evaluation takes place. This function is backwards competible with Moscow MI 1.44 and earlier. Equivalent to compileStructure [] "U.sml".

below); otherwise compilation will be silent. In any case, compilation warnings are reported, and compilation errors abort the compilation and raise the exception Fail with a string argument. The declared identifiers will be reported if verbose is true (see

compileStructure opnunits "U.sig"] compiles the specifications

The result is a in file U.sig as if they form a signature declaration signature U = sig ... contents of U.sig ... end The contents of popunits is added to the compilation context in which the specifications in U.sig are compiled. The result is a compiled signature file U.ui. This

compiled signature file U.ui. This corresponds to invoking the batch compiler as follows: mosmLc -c Ul.ui... Un.ui -structure U.sig where opnunits equals ["Ul", ..., "Un"].

compileStructure opnunits "U.sml"] compiles the declarations in

already and represents a signature called U then the compiled declarations are matched against it. The result is a bytecode file U.uo. If no file U.ui existed, then also a file U.ui is created, containing the inferred signature of structure U. This corresponds to invoking the batch compiler as follows:

mosmic -c UI.ui ... Un.ui -structure U.sml
where opnunits equals ["UI", ..., "Un"]. The contents of opmunits is added to the compilation context in which the declarations in U.sml are compiled. If U.ui exists already and accommendations of the declarations in U.sml are compiled. file U.sml as if they formed a structure declaration structure U = struct ... contents of U.sml ... e

compileToplevel opnunits "U.sig"] compiles the specifications in file U.sig, in a context in which all declarations from opnunits are visible, creating a compiled signature file U.ui. This corresponds to invoking the batch compiler as follows: mosmile - C Ul.ui ... Un.ui - roplevel U.sig

mosmlc -c UI.ui ... Un.ui -toplevel U.sig where opnunits equals ["UI", ..., "Un"].

[compileToplevel opnunits "U.sml"] compiles the declarations in

the This corresponds to invoking file U.sml, in a context in which all declarations from opnunits are visible, creating a bytecode file U.uo. If U.ui exists already, then the compiled declarations are matched against it; otherwise the file U.ui is created. This corresponds to invoki

63

mosmic -c Ul.ui ... Un.ui -toplevel U.sml where opnumits equals ["Ul", .... "Γኩ"] batch compiler as follows mosmlc -c Ul.ui ... U

load "U"] will load and evaluate the compiled unit body from file any other unit is U.W. The resulting values are not reported, but exceptions are reported, and cause evaluation and loading to stop. If U is already loaded, then load "U" has no effect. If any other mentioned by U but not yet loaded, then it will be loaded automatically before U.

Opening it After loading a unit, it can be opened with 'open U'. Openi at top-level will list the identifiers declared in the unit. When loading U, it is checked that the signatures of units mentioned by U agree with the signatures used when compiling U, and it is checked that the signature of U has not been modified since U was compiled; these checks are necessary for type safety. The exception Fail is raised if these signature checks fail, or if the file containing U or a unit mentioned by U does not exist. The

loadOne "U"] is similar to 'load "U"', but raises exception Fail if U is already loaded or if some unit mentioned by U is not yet loaded. That is, it does not automatically load any units mentioned by U. It performs the same signature checks as 'load' [loaded ()] returns a list of the names of all compiled units that have been loaded so far. The names appear in some random order.

searched for interface files ("in files), bytecode files ("uo files), and source files (sml files). This variable affects the load, loadone, and use functions. The current directory is always searched first, followed by the directories in loadpath, in order. By default, only the standard library directory is in the list, but if additional directories are specified using option -I, then these directories are prepended to loadpath. [loadPath] determines the load path: which directories will be

[quietdec] when true, turns off the interactive system's prompt and responses, except warnings and error messages. Useful for writing scripts in SML. The default value is false; can be set to true with the -quietdec command line option.

compile will be printed. The printed signature follows the syntax of Moscow ML signatures, so the output of compile "U.sml" can be edited to subsequently create file U.sig. The default value is [verbose] determines whether the signature inferred by a call to ref false.

for a brief explanation of quotations. When quotation is false, the backquote character is an ordinary symbol which can be used in ML symbolic identifiers. When quotation is true, the backquote character is illegal in symbolic identifiers, and a quotation 'a b c' will be recognized by the parser and evaluated to an object of permitted in declarations entered at top-level and in files compiled with compile. A quotation is a piece of text surrounded by backquote characters 'a b c' and is used to embed object language phrases in ML programs; see the Moscow ML Owner's Manual are quotation] determines whether quotations and antiquotations False by default type 'a General.frag list.

variables, and type variables are generalized only in bindings to non-expansive expressions. Non-generalized type variables are left free, to be instantiated when the bound identifier is used. An expression is non-expansive if it is a variable, a special valuepoly] determines whether value polymorphism is used or not in the type checker. With value polymorphism (the default), there is no distinction between imperative  $('\_a)$  and applicative ('a) type

constant, a function, a tuple or record of non-expansive expressions, a parenthesized or typed non-expansive expression, or the application of an exception or value constructor (other than ref) to a non-expansive expression. If valuepoly is false, then the type checker will distinguish imperative and applicative type variables, generalize all applicative type variables, and generalize imperative type variables only in non-expansive expressions. True by default.

Module Mosml

65

Mosml -- some Moscow ML specific functions

val argv : unit -> string list val time : ('a -> 'b) -> ('a -> 'b) val list string -> string list val list val doubleVec : real -> Word8Vector.vector val vecFloat : Word8Vector.vector -> real val floatVec : real -> Word8Vector.vector val vecFloat : Word8Vector.vector val wecFloat : Word8Vector.vector val md5sum : string -> string

Success of string datatype runresult =

val run : string -> string list -> string -> runresult

[argv ()] returns the command line strings of the current process. Hence List.nth(argv (), 0) is the command used to invoke the SML process, List.nth(argv (), 1) is its first argument, and so on. We recommend using the SML Basis Library CommandLine structure instead.

[time f arg] applies f to arg and returns the result; as a side effect, it prints the time (cpu, system, and real time) consumed by the evaluation.

[listDir path] returns the list of all files and subdirectories of the directory indicated by path. Raises OS.SysErr in case of failure.

[doubleVec r] returns an eight-element vector of Word8.word, which contains the real number in the IEEE 754 floating-point 'double format' bit layout stored in big-endian (high byte first) order.

and [vecDouble v] accepts an eight-element vector v of Word8.word, an returns the real number obtained by taking v to be an IEEE 754 floating-point 'double format' number stored in big-endian (high byte first) order. Raises Fail if v is not en eight-element

[floatVec r] returns a four-element vector of Word8.word, which contains the real number in the IEEE 754 floathing-point 'float format' bit layout stored in big-endian (high byte first) order. Raises Fail if r is not representable as a 32-bit float.

[vecFloat v] accepts a four-element vector v of Word8.word, and returns the real obtained by taking v to be an IEEE 754 floating-point 'Incomat' number stored in big-endian (high byte first) order. Raises Fail if v is not a four-element vector.

[md5sum s] computes the 128-bit MD5 checksum of string s and returns it as a 22 character base64 string.

[run cmd args inp] executes the program cmd with command-line arguments args and standard input inp. Returns Success s where s is the program's (standard and error) output as a string, if it executed successfully; otherwise returns Failure s where s is its (standard and error) output as a string.

Ø The Mosmlegi library is for writing CGI programs in Moscow ML. GGI program may be installed on a WWW server and is invoked in response to HTTP requests sent to the server from a web browser, typically from an HTML PORM element.

[cgi\_fieldhames] is a list of the names of fields present in the CGI call message. If field name frm is in cgi\_fieldhames, then cgi\_field\_string frm <> NONE.

67

[cgi\_field\_strings fnm] is a (possibly empty) list of the strings bound to field fnm.

to [cgi\_field\_string fnm] returns SOWE(s) where s is a string bound field name fnm, if any; otherwise NONE. Equivalent to case cgi\_field\_strings fnm of

=> NONE

| s :: \_ => SOME s

[ogi\_field\_integer (frm, deflt)] attempts to parse an integer from field fnm. Returns i if ogi\_field\_string(fnm) = SOME(s) and an integer i can be parsed from a prefix of s; otherwise returns deflt.

2. Obtaining field values sent with ENCTYPE="multipart/form-data"

cgi\_partnames] is a list of the names of the parts of multipart/form-data message.

part The type part is the abstract type of parts of a message. Each p may have several fields. In this implementation, the field of a part cannot be a another part itself. [cgi\_parts pnm] is a (possibly empty) list of the parts called pnm.

[ogi\_part pnm] is SOME(prt) where prt is a part called pnm, if any; otherwise NONE. Equivalent to rwise NONE. Equivalent to case cgi\_parts pnm of

prt :: \_ => SOME prt => NONE

part\_fieldnames prt] is the list of field names in part pnm.

part\_type prt] is SOME(typ) if the part prt contains a specification Context-Type: typ'; otherwise NONE.

the [part\_data prt] is the data contain in part prt; for instance, contents of a file uploaded via form-based file upload.

[part\_field\_strings prt fnm] is a (possibly empty) list of strings bound to field fnm in part prt.

[part\_field\_string prt fnm] returns SOME(s) where s is a string bound to field name fnm in part prt, if any; otherwise NOME. case part\_field\_strings prt fnm of Equivalent to

| S :: \_ => SOME S => NONE

[part\_field\_integer prt (fnm, deflt)] attempts to parse an integer = SOME (s) and an integer i can be parsed from a prefix of s; otherwise returns deflt.

3. Administrative and server information

Each of the following variables has the value SOME(s) if the corresponding CGI environment variable is bound to string s; otherwise NONE:

[cgi\_server\_software] is the value of SERVER\_SOFTWARE

[cgi\_server\_name] is the value of SERVER\_NAME

<sup>1.</sup> Obtaining field values sent from an ordinary HTML form

WOSMLCGI

```
[cgi_http_proxy_connection] is the value of HTTP_PROXY_CONNECTION
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  [ogi_content_length] is the value of CONTENT_LENGTH, that is, length of the data transmitted in the CGI call.
[cgi_gateway_interface] is the value of GATEWAY_INTERFACE
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  [cgi_annotation_server] is the value of ANNOTATION_SERVER
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             [cgi_request_filename] is the value of REQUEST_FILENAME
                                                                                                                                                                                                                                                                                                                                                                                                        [cgi_http_user_agent] is the value of HTTP_USER_AGENT
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           [cgi_path_translated] is the value of PATH_TRANSLATED
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           cgi_script_filename] is the value of SCRIPT_FILENAME
                                                                           [cgi_server_protocol] is the value of SERVER_PROTOCOL
                                                                                                                                                                                                                                          [cgi_request_method] is the value of REQUEST_METHOD
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             cgi_http_forwarded] is the value of HTTP_FORWARDED
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               cgi_document_root] is the value of DOCUMENT_ROOT
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   cgi_content_type] is the value of CONTENT_TYPE
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          [cgi_server_admin] is the value of SERVER_ADMIN
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            [cgi_http_referer] is the value of HTTP_REFERER
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      [cgi_query_string] is the value of QUERY_STRING
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        cgi_remote_ident] is the value of REMOTE_IDENT
                                                                                                                                                                                                                                                                                                                cgi_http_accept] is the value of HTTP_ACCEPT
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      [cgi_script_name] is the value of SCRIPT_NAME
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     cgi_remote_host] is the value of REMOTE_HOST
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  cgi_http_cookie] is the value of HTTP_COOKIE
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         [cgi_remote_addr] is the value of REMOTE_ADDR
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         [cgi_remote_user] is the value of REMOTE_USER
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          cgi_api_version] is the value of API_VERSION
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         cgi_the_request] is the value of THE_REQUEST
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    cgi_request_uri] is the value of REQUEST_URI
                                                                                                                                                          [cgi_server_port] is the value of SERVER_PORT
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       cgi_path_info] is the value of PATH_INFO
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        [cgi_auth_type] is the value of AUTH_TYPE
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        cgi_is_subreq] is the value of IS_SUBREQ
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 cgi_http_host] is the value of HTTP_HOST
```

MOSMLCOOKIE 69

### Module Mosmicookie

These functions may be used in CGI scripts to get and set cookies.

(c) Hans Molin, Computing Science Dept., Uppsala University, 1999.

[getCookieValue ck] returns SOME(v) where v is the value associated with the cookie ck, if any; otherwise returns NONE.

[getCookie ck] returns SOME(nv) where nv is the ck=value string for the cookie ck, if any; otherwise returns NONE.

[allCookies] is a list [nvl, nv2, ..., nvm] of all the ck=value pairs of defined cookies.

[setCookie { name, value, expiry, domain, path, secure } ] returns a string which (when transmitted to a browser as part of the HTTP response header) sets a cookie with the given name, value, expiry date, domain, path, and security.

[setCookies ckds] returns a string which (when transmitted to a browser as part of the HTTP response header) sets the specified cookies.

[deleteCookie { name, path } ] returns a string which (when transmitted to a browser as part of the HTTP response header) sets the specified cookie by setting its expiry to some time in the past.

#### Module Msp

70

```
Msp -- utilities for CGI scripts and ML Server Pages
```

Efficiently concatenable word sequences

datatype wseq = The empty sequence
Empty Newline Newline A string
| \$ of string list A sequence of strings | \$ & of wseq \* wseq; Concatenation of sequences

#### Manipulating wseqs

val prmap : ('a -> wseq) -> 'a list -> wseq
val prsep : wseq -> ('a -> wseq) -> 'a list -> wseq
val flatten : wseq -> string
val printseq : wseq -> unit
val vec2list : 'a vector -> 'a list

# Shorthands for accessing CGI parameters

exception ParamMissing of string
exception NotInt of string \* string
val % : string -> bool
val % : string -> int
val % : string \* string
val % : string \* string
val % : string \* string -> int

#### HTML generic marks

val mark0 : string -> wseq
val mark0a : string -> string -> wseq
val mark1 : string -> wseq -> wseq
val mark1a : string -> string -> wseq
val comment : wseq -> wseq

# HTML documents and headers

val html : wseq -> wseq
val head : wseq -> wseq
val title : wseq -> wseq
val body : wseq -> wseq
val bodya : string -> wseq -> wseq
val htmldoc : wseq -> wseq

# HTML headings and vertical format

 val hl
 wseq -> wseq

 val h2
 wseq -> wseq

 val h3
 wseq -> wseq

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          In general, multiple strings may be associated with a CGI parameter; use Mosmlcgi.cgi_field_strings if you need to access all of them.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            [%# fnm] returns the integer i if there is a string associated with CGI parameter fnm, and that string is parsable as ML integer i. Raises ParamWissing(fnm) if no string is associated with fnm. Raises NotInt(fnm, s) if there is a string but it is not parsable
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           it to

                                                                                                                                                                                                                                                                                                                                                                                                                                                                       This module provides support functions for writing CGI scripts and {
m ML} Server Page scripts.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  \{\$ \# (fnm,\ dflt)\} returns the integer i if there is a string associated with CGI parameter fnm, and that string is parsable as
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             [wseq] is the type of efficiently concatenable word sequences. Building an HTML page (functionally) as a wseq is more efficient than building it (functionally) as a string, and more convenient and modular than building it (imperatively) by calling print.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          [prmap f xs] is f xl && ... && f xn evaluated from left to right, when xs is [x1, ..., xn].
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          [pxsep sep f xs] is f xl && sep && ... && sep && f xn, evaluated from left to right, when xs is [xl, ..., xn].

an ML int; otherwise returns the string dflt.

HTML generic marks:

as a wsed. [mark0 t] generates the HTML tag <t>

<t attr> as a wseq. [mark0a attr t] generates the attributed HTML tag

mark1 t ws] generates <t>ws</t> as a wseq

<t attr>ws</t> as a wseq. [markla attr t ws] generates

[comment ws] generates <!--ws--> as a wseq.

HTML documents and headers:

[html ws] generates <HTML>ws</HTML>.

[head ws] generates <HEAD>ws</HEAD>

[title ws] generates <TITLE>ws</TITLE>

[body ws] generates <BODY>ws</BODY>

[bodya attr ws] generates <BODY attr>ws</BODY>

[htmldoc titl ws] generates <HTML><HEAD><TITLE>titl</TITLE></HEAD><BODY>ws</BODY></HTML>.

HTML headings and vertical format:

[h1 ws] generates <H1>ws</H1>

[p ws] generates <P>ws</P>

[pa attr ws] generates <P attr>ws</P>

[br] generates <BR>

attr> [bra attr] generates <BR

[hr] generates <HR>

[hra attr] generates <HR

[divi ws] generates <DIV>ws</DIV>.

[divia attr ws] generates <DIV attr>ws</DIV>

[blockquote ws] generates <BLOCKQUOTE>ws</BLOCKQUOTE>

[blockquotea attr ws] generates <BLOCKQUOTE attr>ws</BLOCKQUOTE>

center ws] generates <CENTER>ws</CENTER>

[address ws] generates <ADDRESS>ws</ADDRESS>

[pre ws] generates <PRE>ws</PRE>

HTML anchors and hyperlinks:

[ahref link ws] generates <A HREF="link">ws</A>

[ahrefa link attr ws] generates <A HREF="link" attr>ws</A>.

[aname nam ws] generates <A NAME="name">ws</A>

HTML text formats and style:

[em ws] generates <EM>ws</EM>

[strong ws] generates <STRONG>ws</STRONG>

[tt ws] generates <TT>ws</TT>

[sub ws] generates <SUB>ws</SUB>

[sup ws] generates <SUP>ws</SUP>

[fonta attr ws] generates <FONT attr>ws</FONT>.

HTML lists:

[ul ws] generates <UL>ws</UL>.

[ula attr ws] generates <UL attr>ws</UL>.

[ol ws] generates <0L>ws</0L>.

[ola attr ws] generates <0L attr>ws</0L>.

[li ws] generates <LI>ws</LI>.

[dl ws] generates <DL>ws</DL>.

[dla attr ws] generates <DL attr>ws</DL>.

[dt ws] generates <DT>ws</DT>.

[dd ws] generates <DD>ws</DD>.

HTML tables:

[table ws] generates <TABLE>ws</TABLE>

[tablea attr ws] generates <TABLE attr>ws</TABLE>.

tr ws] generates <TR>ws</TR>

[tra attr ws] generates <TR attr>ws</TR>

[td ws] generates <TD>ws</TD>.

[tda attr ws] generates <TD attr>ws</TD>.

[th ws] generates <TH>ws</TH>

[tha attr ws] generates <TH attr>ws</TH>.

[caption ws] generates <CAPTION>ws</CAPTION>

captiona attr ws] generates <CAPTION attr>ws</CAPTION>

HTML images and image maps:

[img s] generates <IMG SRC="s">.

[imga s attr] generates <IMG SRC="s" attr>.

[map nam ws] generates <MAP NAME="name">ws</MAP>

[mapa nam attr ws] generates <MAP NAME="name" attr>ws</MAP>.

[area { alt, coords, href, shape}] generates <AREA SHAPE="shape" COORDS="coords" HREF="link" ALT="desc">
when href is SOME link (where HREF is replaced by NOHREF otherwise)

is SOME desc (where ALT is omitted otherwise). alt and

75

HTML forms etc:

[form act ws] generates <FORM ACTION="act">ws</FORM>

[forma act attr ws] generates <FORM ACTION="act" attr>ws</FORM>.

[input typ] generates <INPUT TYPE=typ>

[inputa typ attr] generates <INPUT TYPE=typ attr>.

intext name attr] generates <INPUT TYPE=TEXT NAME="name" attr>.

inpassword name attr] generates <INPUT TYPE=PASSWORD NAME="name" attr>.

[incheckbox {name, value} attr] generates <INDUT TYPE=CHECKBOX NAME="name" VALUE="value" attr>.

[inradio {name, value} attr] generates <INPUT TYPE=RADIO NAME="name" VALUE="value" attr>.

[inreset value attr] generates <INPUT TYPE=RESET VALUE="value" attr>.

insubmit value attr] generates <INPUT TYPE=SUBMIT VALUE="value" attr>.

[inhidden {name, value}] generates
<INPUT TYPE=HIDDEN NAME="name" VALUE="value">.

[textarea name ws] generates <TEXTAREA NAME="name">ws</TEXTAREA>

[textareaa name attr ws] generates <TEXTAREA NAME="name" attr>ws</TEXTAREA>.

select name attr ws] generates <SELECT NAME="name" attr>ws</SELECT>

option value] generates <OPTION VALUE="value">.

HTML frames and framesets:

frameset attr ws] generates <FRAMESET attr>ws</FRAMESET>.

[frame { src, name }] generates <FRAME SRC="src" NAME="name">.

[framea { src, name } attr] generates <FRAME SRC="src" NAME="name" attr>

HTML encoding functions:

[urlencode s] returns the url-encoding of s. That is, space (ASCII 32) is replaced by '+' and every non-alphanumeric character c except the characters -\_ is replaced by %th, where hh is the hexadecimal representation of the ASCII code of c.

[htmlencode s] returns the html-encoding of s. That is, < and > are replaced by &lt; and &gt; respectively, and & is replaced by &amp;

[openbase { dbhost, dbport, dboptions, dbtty, dbname, dbuser, dbpwd }] opens a connection to a MySQL database server on the given host (default the local one) on the given port (default ?), to the given database (defaults to the user's login name), for the given user name (defaults to the current user's login name), and the given user password (default none). The result is a connection which may be used in subsequent queries. In MySQL, unlike PostgreSQL, the dboptions and dbtty fields are not used. [options dbconn] returns the options given when opening the database reset dbconn] attempts to close and then reopen the connection to [host dbconn] returns SOME h, where h is the database server host status dbconn] returns true if the connection is usable, false name, if the connection uses the Internet; returns NONE if the connection is to a socket on the local server. [closebase dbconn] closes the database connection. No further tty dbconn] returns the name of the tty used for logging. port dbconn] returns the port number of the connection. db dbconn] returns the name of the database. queries can be executed the database server

dbresult] is the type of result sets from MySQL queries.

[dbconn] is the type of connections to a MySQL database.

[errormessage dbconn] returns NONE if no error occurred, and SOME msg

MySQL time hh:mm:ss

Date of int \* int \* int Time of int \* int \* int

String of string

if an error occurred, where msg describes the error

execute dbconn query] sends an SQL query to the database server for execution, and returns a resultset dbres

[resultstatus dbres] returns the status of the result set After a select query that succeeded, it will be Tuples\_ok.

set ntuples dbres] returns the number of tuples in the result after a query

 $[\mbox{omdtuples}\ d\mbox{bres}]$  returns the number of tuples affected by an insert, update, or delete  $\mbox{SQL}\ \mbox{command}.$ 

nfields dbres] returns the number of fields in each tuple after

fname dbres fno] returns the name of field number fno (in the result set after a query). The fields are numbered 0, fnames dbres] returns a vector of the field names (in the result set after a query). [fnumber dbres fname] returns SOME i where i is the number (0, 1, ...) of the field called fname (in the result set after a query), if the result set contains such a field name; returns NOME otherwise.

[ftype dbres fno] returns the dyntype of field number fno (in the result set after a query).

[ftypes dbres] returns a vector of the dyntypes (in the result set after a query)

[fromtag dt] returns the name of the preferred MySQL type used to represent values of the dyntype dt. This may be used when to represent values of the dyntype dt. building 'create table' statements.

getint dbres fno tupno] returns the integer value of field number ino in tuple tupno of result set dbres. Raises Null if the value is NULL. (getreal dbres fno tupno) returns the floating-point value of field number fno in tuple tupno of result set dbres. Raises Null if the number fno in tuple tupno of result set dbres. [getstring dbres fno tupno] returns the string value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL

[getdate dbres fno tupno] returns the date (yyyy, mth, day) value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL. Raises Fail if the field cannot be scanned as a date.

[gettime dbres fno tupno] returns the time-of-day (hh, mm, ss) value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL. Raises Fail if the field camnot be scanned as a time.

getbool dbres fno tupno] returns the boolean value of field number in in tuple tupno of result set dbres. Raises Null if the value (getdatetime dbres fno tupno) returns the Date.date value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL. Raises Fail if the field cannot be scanned as a

[isnull dbres fno tupno] returns true if the value of field number fno in tuple tupno of result set dbres is NULL; false otherwise.

getdynfield dbres fno tupno] returns the value of field number fno

MYSOL

2

in tuple tupno of result set dbres as a dynval (a wrapped value). A NULL value is returned as NullVal. Note that the partial application (getdynfield dbres fno) precomputes the type of the field fno. Hence it is far more efficient to compute

ifno. Hence it is far more efficient to compute let val getfno = getdynfield dbres fno in tabulate(ntuples dbres, getfno) end

than to compute

let fun getfno tupno = getdynfield dbres fno tupno
in tabulate(ntuples dbres, getfno) end
because the latter repeatedly computes the type of the field.

(getdyntup dbres tupno) returns the fields of tuple tupno in result set dbres as a vector of dynvals.

getdyntups dbres] returns all tuples of result set dbres as vector of vectors of dynvals.

[dynval2s dv] returns a string representing the dynval dv.

[applyto x f] computes f(x). This is convenient for applying several functions (given in a list or vector) to the same value: map (applyto 5) (tabulate(3, getdynfield dbres))

[getdynfield dbres 0 5, getdynfield dbres 1 5, getdynfield dbres 2 5]

[copytableto(dbconn, tablename, put)] simulates a PostgreSQL "COPY TABLE TO" statement, applies the function put to every tuple of the table, represented as a line of text (not terminated by newline (h), and cleans up at the end. For instance, to copy the contents of a table t to a text stream s (one tuple on each line), define fun put line = table,

(TextIO.output(s, line); TextIO.output(s, "\n")) and execute

copytableto(dbconn, "t", put).

[copytablefrom(dbconn, tablename, useput)] simulates a PostgreSQL "COPY TABLE FROM" statement, creates a put function for copying lines to the table, passes the put function to useput, and cleans up at the end. The put function may be called multiple times for each line (tuple); the end of each line is indicated by the newline character "\n" as usual. For instance, to copy the contents of a text stream s to a table t, define

while not (TextIO.endOfStream s) do put(TextIO.inputLine s); fun useput put and execute

copytablefrom(dbconn, "t", useput).
Note that TextIO.inputLine preserves the newline at the end of each

[formattable dbresult] returns a wseq representing an HTML table. The HTML table has a column for every field in the dbresult. The first row is a table header giving the names of the fields in the dbresult. The remaining rows correspond to the tuples in the dbresult, in the order they are provided by the database server. Null fields are shown as NULL.

[showquery dbconn query] sends the SQL query to the database server, then uses formattable to format the result of the query.

The commands This structure provides tools for creating customized Oppen-style pretty-printers, based on the type ppstream. A ppstream is an output stream that contains prettyprinting commands. The commands are placed in the stream by various function calls listed below.

There following primitives add commands to the stream: begin\_block, end\_block, add\_string, add\_break, and add\_newline. All calls to add\_string, add\_break, and add\_newline must happen between a pair of calls to begin\_block and end\_block must be properly nested dynamically. All calls to begin\_block and end\_block must be properly nested (dynamically).

[ppconsumer] is the type of sinks for pretty-printing. A value of type ppconsumer is a record of a string consumer, a specified linewidth, and a flush function which is called whenever flush ppstream is called. : string -> unit, linewidth: int, consumer

A prettyprinter can be called outright to print a value. In addition, a prettyprinter for a base type or nullary datatype ty can be installed in the top-level system. Then the installed prettyprinter will be invoked automatically whenever a value of type ty is to be printed.

break\_style] is the type of line break styles for blocks:

[CONSISTENT] specifies that if any line break occurs inside the block, then all indicated line breaks occur. block, then all [INCONSISTENT] specifies that breaks will be inserted to only avoid overfull lines.

[mk\_ppstream {consumer, linewidth, flush}] creates a new ppstream
which invokes the consumer to output text, putting at most
linewidth characters on each line.

dest\_ppstream ppstrm] extracts the linewidth, flush function, and consumer from a ppstream.

[add\_break ppstrm (size, offset)] notifies the pretty-printer that a line break is possible at this point.
\* When the current block style is CONSINENT:
\*\* if the enrire block fits on the remainder of the line, then

output size spaces; else \*\* increase the current indentation by the block offset;

ЬР PP86

further indent every item of the block by offset, and add
one newline at every add presh in the block.

\* When the current block style is INCONSISTENT:

\*\* if the next component of the block fits on the remainder of
the line, then output size spaces; else

\* issue a newline and indent to the current indentation level
plus the block offset plus the offset.

[add\_newline ppstrm] issues a newline.

[add\_string ppstrm str] outputs the string str to the ppstream.

[begin\_block ppstrm style blockoffset] begins a new block and level of indentation, with the given style and block offset.

end\_block ppstrm] closes the current block.

[clear\_ppstream ppstrm] restarts the stream, without affecting the underlying consumer.

[flush\_postream postrm] executes any remaining commands in the ppstream (that is, flushes currently accumulated output to the consumer associated with ppstrm); executes the flush function associated with the consumer; and calls clear\_postream.

[with\_pp consumer f] makes a new ppstream from the consumer and applies f (which can be thought of as a producer) to that ppstream, then flushed the ppstream and returns the value of f.

[pp\_to\_string linewidth printit x] constructs a new ppstream ppstrm whose consumer accumulates the output in a string s. Then evaluates (printit ppstrm x) and finally returns the string s.

Example 1: A simple prettyprinter for Booleans:

```
begin_block pps INCONSISTENT 6;
add_string pps (if d then "right" else "wrong");
end_block pps
fun ppbool pps d = let open PP
                                                                                                                            end;
```

Now one may define a ppstream to print to, and exercise it:

```
fn () => TextIO.flushOut TextIO.stdOut};
                          fn s => TextIO.output(TextIO.stdOut, s),
linewidth = 72,
val ppstrm = PP.mk_ppstream {consumer =
                                                                                   flush
```

fun ppb b = (ppbool ppstrm b; PP.flush\_ppstream ppstrm);

- ppb false; wrong> val it = () : unit

The prettyprinter may also be installed in the toplevel system; then it will be used to print all expressions of type bool subsequently computed: > val it = wrong : bool > val it = ( $\hat{)}$ : unit - 1=0; - installPP ppbool;

See library Meta for a description of installPP.

- 1=1; > val it = right : bool

Example 2: Prettyprinting simple expressions (examples/pretty/ppexpr.sml):

87

```
val e1 = Cst 1;
val e2 = Cst 2;
val e2 = Dus(e1, Neg e2);
val e4 = Plus(Neg e3, e3);
val e5 = Plus(Neg e4, e4);
val e6 = Plus(e6, e6);
val e7 = Plus(e6, e6);
val e8 = Plus(e3, Plus(e3, Plus(e3, Plus(e3, e7)))));
                                                                                                                             = add_string pps (Int.toString i)
= (add_string pps "~"; ppe e)
                                                                                                                                                                ppe (Plus(el, e2)) = (begin_block pps CONSISTENT 0;
    add_string pps "(";
                                                                                                                                                                                                      ppe_el;
add_string pps " + ";
add_break pps (0, 1);
                                                                                                                                                                                                                                                        ppe e2;
add_string pps ")";
end_block pps)
                                                                                                                                                                                                                                                                                                                                 begin_block pps INCONSISTENT 0;
                                                                                                                                                                                                                                                                                                                                                                                                                         val _ = installPP ppexpr;
                                                                                                         let open PP fun ppe (Cst i)
                                                                                                                                                                                                                                                                                                                                                                                                                                                               Some example values:
                                                        Plus of expr * expr
                                                                                                                                                                                                                                                                                                                                                   ppe e0;
end_block pps
                                                                                            fun ppexpr pps e0 =

```

88 PARSIN

# **Module Parsing**

Parsing -- runtime library for parsers generated by mosmlyac Based on the runtime library for camlyacc; copyright 1993 INRIA, France

local open Vector Obj Lexing in

val symbolStart : unit -> int
val symbolEnd : unit -> int
val itemStart : int -> int
val itemEnd : int -> int
val clearParser : unit -> unit

For internal use in generated parsers:

type parseTables = actions (unit -> obj) vector \* trans1 string \* lbs string \* defred string \* doto string \* string sindex string \* sindex string \* sindex string \* string trablesize int \* table string \* table string \* string tablesize string \* tablesize string \* string table string \* string

exception yyexit of obj exception ParseError of (obj -> bool) val yyparse : parseTables -> int -> (lexbuf -> 'a) -> lexbuf -> 'b val peekVal : int -> 'a

end

These functions are for use in mosmlyac-generated parsers. For further information, see the Moscow MIC Owner's Manual. For examples, see mosml/examples/lexyacc and mosml/examples/calc.

A grammar definition (input to mosmlyac) consists of fragments of this form

nonterm :
grsyms1 { action1 }
| grsyms2 { action2 }
| grsyms3 { action3 }
| ...

where the grsyms are sequences of grammar symbols, matching some string of characters, and the actions are corresponding semantic actions, written in ML. The following functions can be used in the semantic actions:

[symbolStart ()] returns the start position of the string that matches the sequence of grammar symbols. The first character in the input stream has position 0. May be called in a semantic action only.

[symbolEnd ()] returns the end position, plus one, of the string that matches the sequence of grammar symbols. The first character in the input stream has position 0. May be called in a semantic action only.

[itemStart i] returns the start position of the string that matches the i'th grammar symbol in the sequence. The first grammar symbol has number 1. The first character in the input stream has position 0. May be called in a semantic action only.

ARSING

68

[itemEnd i] returns the end position, plus one, of the string that matches the i'th grammar symbol in the sequence. The first grammar symbols has number 1. The first character in the input stream has position 0. May be called in a semantic action only.

[clearParser ()] clears the parser stack. It may be called after a parsing function has returned, to remove all pointers from the parser stack to structures that were built by semantic actions during parsing. This is not strict necessary, but reduces the memory requirements of the program.

PATH 6

#### **Module Path**

```
Basis Library
 OS. Path -- SML
                                             parentArc currentArc
                       exception Path
                                              val
```

joinDirFile : {dir : string, file : string} -> string
dir : string -> string
file : string -> string : string -> string : string -> string val val val

This module provides OS-independent functions for manipulating strings that represent file names and paths in a directory structure. None of these functions accesses the actual filesystem.

#### Definitions:

\* An arc denotes a directory or file. Under Unix or DOS, an arc have form "..., ".", "., or "abc", or similar.

\* An absolute path has a root: Unix examples include "/", "/a/b"; DOS examples include "\", "\a\b", "A:\a\b".

\* A relative path is one without a root: Unix examples include "..", "a/b"; DOS examples include "..", "a\b", "A:a\b".

Under Unix, there is only one \* A path has an associated volume. Under Unix, there is on volume, whose name is "". Under DOS, the volume names are "A:", "C:", and similar.

\* A canonical path contains no occurrences of the empty arc "" or the current arc ".", and contains or the parent arc ".." only at the beginning and only if the path is relative.

That is, \* All functions (except concat) preserve canonical paths. if all arguments are canonical, then so will the result be. \* All functions are defined so that they work sensibly on canonical

\* There are three groups of functions, corresponding to three ways to look at paths, exemplified by the following paths:

/d/e/f/a.b.c A:d\e\f\a.b.c

and

d/e/f/a.b.c A:d\e\f\a.b.c

PATH

6

(1) A path consists of a sequence of arcs, possibly preceded volume and a root:

_ '	
1 1	. 4
מ	ו ממ
arc	44
1	שט
<u>-</u>	סס
vol root	<b>\</b>
	A
n	a.b.c
arcs	4141
	שש
<u>-</u> ¦	סס
vol	A:
	nix examples: OS examples:

- I D

(2) A path consists of a directory part and a (last) file name part:

	/f a.b.c \e\f a.b
file dire	.b.c /d/.
directory	d/e/f A:d\e\f
	nix examples OS examples:

(3) A path consists of a base and an extension:

extension	υД
base	/d/e/f/a.b A:\d\e\f\a
extension	D, U
base	d/e/f/a.b A:d\e\f\a
	Unix examples: DOS examples:

GROUP 0: General functions on paths:

[parentArc] is the arc denoting a parent directory: ".." under DOS and Unix.

[currentArc] is the arc denoting the current directory: "." under DOS and Unix.

[isRelative p] returns true if p is a relative path.

[isAbsolute p] returns true if p is an absolute path. Equals not (isRelative p). [validVolume {isAbs, vol}] returns true if vol is a valid volume name for an absolute path (if isAbs=true) resp. for a relative path (if isAbs=false). Under Unix, the only valid volume name is ""; under MS DOS and MS Windows the valid volume names are "", "a:",

[getParent p] returns a string denoting the parent directory of p. It holds that getParent p = p if and only if p is a root.

[concat (pl, p2)] returns the path consisting of pl followed by p2. Does not preserve canonical paths: concat("a/b", "../c") equals "a/b/../c". This is because "a/b/../c" and "a/c" may not be equivalent in the presence of symbolic links. Raises Path if p2 is not a relative path.

[mkAbsolute(pl, p2)] returns the absolute path made by taking path p2, then pl. That is, returns plift pl is absolute; otherwise returns the canonicalized concatenation of p2 and pl. Raises Path if p2 is not absolute (even if pl is absolute).

[mkRelative(pl, p2)] returns pl relative to p2. That is, returns pl if pl is already relative; otherwise returns the relative path leading from p2 to pl. Raises Path if p2 is not absolute (and even if p1 is relative), or if p1 and p2 are both absolute but have different roots.

[mkCanonical p] returns a canonical path which is equivalent to p. Redundant occurrents arc, and the rempty arc are removed. The canonical path will never be empty string; the empty path is converted to the current directory path

[isCanonical p] is equal to (p = mkCanonical p)

GROUP 1: Manipulating volumes and arcs:

92 PAI

[fromString p] returns {isAbs=false, vol, arcs} if the path p is relative, and {isAbs=true, vol, arcs} if the path p is absolute. In both cases vol is the volume name and arcs is the list of (possibly empty) arcs of the path. Under Unix, the volume name is always the empty string ""; under DOS it will have form "A:", "C:", or similar.

[toString path] reconstitutes a path from its root (if any) and arcs. Raises Path if applied to a relative path whose first arc is empty. It holds that toString(fromString p) = p, except that in MS DOS, slashes "\" in p will be replaced by backslashes "\" it holds that fromString (toString p) = p when no exception is raised. It holds that isRelative(toString p) = p when no exception is raised. When no exception is raised.

[getVolume p] returns the volume name of the path p, if given. Under Unix and MacOS, this is always the empty string "", and under MS DOS and MS Windows, it may have form "A:", "B:", ...

# GROUP 2: Manipulating directory paths and file names:

[splitDirFile p] returns {dir, file} where file is the last arc in p, and dir is the path preceding that arc. A typical use is to split a path into the directory part (dir) and the filename (file).

[joinDirFile {dir, file}] returns the path p obtained by extending the path dir with the arc file.

dir p] equals #dir (splitDirFile p).

[file p] equals #file (splitDirFile p).

# GROUP 3: Manipulating file names and extensions:

[splitBaseExt s] returns {base, ext} where ext = NONE if s has no extension, and ext = SOME e if s has extension e; base is the part of s preceding the extension. A path s is considered having no extension if its last arc contains no extension separator (typically ".") or contains an extension separator networt character, or contains an extension separator as its leftmost character. Hence none of "a.b/cd", "a/.login", "a.", "." has an extension.

[joinBaseExt {base, ext}] returns an arc composed of the base name and the extension (if different from NONR). It is a left inverse of splitBaseExt, so joinBaseExt (splitBaseExt s) = s, but the opposite does not hold (since the extension may be empty, or may contain extension separators).

xt s] equals #ext (splitBaseExt s).

[base s] equals #base (splitBaseExt s).

POLYGDBM PATH

93

# Module Polygdbm

Polygdbm -- GNU gdbm persistent polymorphic hashtables -- requires Dynlib

)) table -> 'key | ist
)) table -> 'key | ist : string \* Gdbm. val fastwrite val reorganize withtable listItems listKeys numItems find peek hasKey insert remove map fold add val val val val val val val val

[('key, 'data) table] is the type of an opened table with keys of type 'key and associated values of type 'data. The actual values of type 'key and 'data cannot contain function closures or abstract values. Values involving references (even circular values) can be stored, but the identity of references is preserved only with every single key or value stored, not across several different values.

The Polygdbm table files of are not portable across platforms, because word size and endianness affects the lay-out of values.

A value of type table can be used only in the argument f to the withtable function. This makes sure that the table is closed after use.

[withtable (nam, mod) f] first opens the table db in file nam with mode mod, then applies f to db, then closes db. Makes sure to close db even if an exception is raised during the evaluation of f(db). Raises GdbmError with an informative message in case the fable cannot be opened. E.g. the table cannot be opened for writing, and cannot be opened for writing, and cannot be opened for writing withing if already opened for reading.

[add db (k,v)] adds the pair (k,v) to db. Raises AlreadyThere if there is a pair  $(k,\ )$  in db already. Raises NotWriter if db is not opened in write mode.

[insert db (k, v)] adds the pair (k, v) to db, replacing any pair  $(k, \_)$  at k if present. Raises NotWriter if db is not opened in write mode.

[find(db, k)] returns v if the pair (k, v) is in db; otherwise raises NotFound.

[peek db k] returns SOME v if the pair  $(k,\;v)$  is in db; otherwise returns NOME.

[hasKey(db, k)] returns true if there is a pair  $(k, \_)$  in db; otherwise returns false.

[remove db k] deletes the pair  $(k,\ )$  from the table if present; otherwise raises NotFound. Raises NotWriter if db is not opened in

listKeys db] returns a list of all keys in db in an unspecified

[numItems db] is the number of (key, value) pairs in equivalent to length(listKeys db).

[listItems db] returns a list of all (key, value) pairs in db in some order. Equivalent to List.map (fn key => (key, find(db,key))) (listKeys db)

[app f db] is equivalent to List.app f (listItems db), provided the function f does not change the set of keys in the table.
Otherwise the effect is unpredictable.

[map f db] is equivalent to List.map f (listItems db), provided the function f does not change the set of keys in the table.
Otherwise the result and effect are unpredictable.

[fold f a db] is equivalent to List.foldr (fn ((k, v), r) => f(k, v, r)) a (listItems db) provided the function f does not change the set of keys in the table. Otherwise the result and effect are unpredictable. [fastwrite] can be set to speed up writes to a table. By default, ifsatwrite is false and every write to a table will be followed by file system synchronization. This is safe, but slow if you perform thousands of writes. However, if !fastwrite is true when calling withtable, then writes may not be followed by synchronization, which may speed up writes considerably. In any case, the file system is synchronized before withtable returns.

reorganize db] has no visible effect, but may be called after a lot of deletions to shrink the size of the table file.

95

# **Module Polyhash**

Polyhash -- polymorphic hashtables as in the SML/NJ Library

'data) hash\_table type ('key,

val mkTable : ('\_key -> int) \* ('\_key \*' key -> bool) -> int \* exn -> ('\_key, 'data) hash\_table -> int wal numltems : ('key, 'data) hash\_table -> int wal insert : ('key, 'data) hash\_table -> 'key \* 'data -> unit val insert : ('key, 'data) hash\_table -> 'key \* 'data -> unit -> 'data option -> 'key \* 'data option -> 'key, 'data hash\_table -> 'key -> 'data option -> 'key, 'data hash\_table -> 'key -> 'data option -> 'key, 'data hash\_table -> 'key -> 'data option -> 'key, 'data hash\_table -> 'key -> 'data option -> 'key, 'data hash\_table -> 'key ', 'data list wal listItems : ('key, 'data hash\_table -> 'key, 'data list wal apply : ('key \*' data -> unit) -> ('key, 'data) hash\_table -> 'key, 'data hash\_table -> 'key, 'data hash\_table -> 'key, 'data hash\_table -> '('key, 'data hash\_table -> 'key, 'data hash\_table -> 'it list unit unit Polymorphic hash primitives from Caml Light val numItems val insert val peekInsert val mkTable val val val val val val val

type [('key, 'data) hash\_table] is the type of hashtables with keys of 'key and data values of type 'data.

SZ [mkTable (hashVal, sameKey) (sz, exc)] returns a new hashtable, using hash function hashVal and equality predicate sameKey. The is a size hitt, and exc is the exception raised by function find. It must be the case that sameKey(kl, k2) implies hashVal(kl) = hashVal(k2) for all kl,k2.

[numItems htbl] is the number of items in the hash table.

an [insert htbl (k, d)] inserts data d for key k. If k already had item associated with it, then the old item is overwritten. [find htbl k] returns d, where d is the data item associated with key k, or raises the exception (given at creation of htbl) if there is no such

[peek htbl k] returns SOME d, where d is the data item associated with key k, or NOME if there is no such d.

[peekInsert htbl (k, d)] inserts data d for key k, if k is not already in the table, returning NONE. If k is already in the table, and the associated data value is d', then returns SOME dand leaves the table unmodified.

ģ

[remove htbl k] returns d, where d is the data item associated with key k, removing d from the table; or raises the exception if there is no such d.

listItems htbl] returns a list of the (key, data) pairs in the hashtable.

apply f htbl] applies function f to all (key, data) pairs in the hashtable, in some order. [map f htbl] returns a new hashtable, whose data items have been obtained by applying f to the (key, data) pairs in htbl. The new tables have the same keys, hash function, equality predicate, and exception, as htbl.

not [filter p htbl] deletes from htbl all data items which do satisfy predicate p.

96 POLYHASH

[transform f htbl] as map, but only the (old) data values are used when computing the new data values.

[copy htbl] returns a complete copy of htbl.

[bucketSizes htbl] returns a list of the sizes of the buckets. This is to allow users to gauge the quality of their hashing function.

[hash k] returns the hash value of k, as a positive integer. If k1+k2 then hash(k1) = hash(k2), so this function can be used when creating hashtables. The application hash(k) always terminates, even on  $\gamma v^2$  its structures. (From the Camil Light implementation).

[hash\_param n m k] computes a hash value for k with the same properties as for hash. The parameters n and m give more precise control over hashing. Hashing performs a depth-first, right-to-left traversal of the structure k, stopping after n meaningful nodes were encountered, or m nodes, meaningful or not, were encountered. Meaningful nodes are: integers, floating-point numbers, strings, characters, booleans, references, and constant constructors.

[mkPolyTable (sz, exc)] creates a new hashtable using the polymorphic hash function (hash) and ML equality (op =); the integer sz is a size hint and the exception exc is to be raised by find.

fromtag : dyntype -> string ftype : dbresult -> int -> dyntype ftypes : dbresult -> dyntype Vector.vector val val

val applyto : 'a -> ('a -> 'b) -> 'b

as an HTML table queryFormatting the result of a database

formattable : dbresult -> Msp.wseq showquery : dbconn -> string -> Msp.wseq val formattabl [dbconn] is the type of connections to a PostgreSQL database.

[dbresult] is the type of result sets from SQL queries.

[oid] is the type of PostgreSQL internal object identifiers.

 $\subseteq$ [openbase { dbhost, dbport, dboptions, dbtty, dbname, dbuser, dbpwd opens a connection to a PostgreSQL database server on the given thes given options local one) on the given port (default 5432), with experience of the given options (default the empty string), with error logging on the given options (default?), to the given database (defaults to the current user's login name), for the given user name (defaults to the current user's login name), and the given password (default none). The result is a connection which may be used in subsequent queries.

No further [closebase dbconn] closes the database connection. queries can be executed.

db dbconn] returns the name of the database

[host dbconn] returns SOME h, where h is the database server host name, if the connection uses the Internet; returns NONE if the connection is to a socket on the local server. options dbconn] returns the options given when opening the database.

[port dbconn] returns the port number of the connection

**POSTGRES** 

66

tty dbconn] returns the name of the tty used for logging.

status dbconn] returns true if the connection is usable, false

reset dbconn] attempts to close and then reopen the connection to the database server.

msg [errormessage dbconn] returns NONE if no error occurred, and SOME if an error occurred, where msg describes the error.

[execute dbconn query] sends an SQL query to the database server for execution, and returns a resultset dbres.

dbres [resultstatus dbres] returns the status of the result set After a select query that succeeded, it will be Tuples\_ok.

set ntuples dbres] returns the number of tuples in the result

[cmdtuples dbres] returns the number of tuples affected by insert, update, or delete  ${\rm SQL}$  command.

nfields dbres] returns the number of fields in each tuple after

[fname dbres fno] returns the name of field number fno (in the result set after a query). The fields are numbered 0,  $1,\ldots$ 

[fnames dbres] returns a vector of the field names (in the result set after a query). [fnumber dbres fname] returns SOME i where i is the number (0, 1, ...) of the field called fname (in the result set after a query), if the result set contains such a field name; returns NONE otherwise.

ftypes dbres] returns a vector of the dyntypes (in the result set [ftype dbres fno] returns the dyntype of field number fno (in the result set after a query).

[fromtag dt] returns the name of the preferred PostgreSQL type used after a query).

This may be used when

[getint dbres fno tupno] returns the integer value of field number fno in tuple tupno of result set dbres. Raises Null if the value to represent values of the dyntype dt. building 'create table' statements.

is NULL.

[getreal dbres fno tupno] returns the floating-point value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL.

[getstring dbres fno tupno] returns the string value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL.

[getdate dbres fno tupno] returns the date (yyyy, mth, day) value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL. Raises Fail if the field cannot be scanned as a date. [gettime dbres fno tupno] returns the time-of-day (hh, mm, ss) value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL. Raises Fail if the field cannot be scanned as a time.

[getdatetime dbres fno tupno] returns the Date.date value of field number fno in tuple tupno of result set dbres. Raises Null if the value is NULL. Raises Fail if the field cannot be scammed as a

date.

[getbool dbres fno tupno] returns the boolean value of field number fno in tuple tupno of result set dbres. Raises Mull if the value is NULL.

[isnul] dbres fno tupno] returns true if the value of field number fno in tuple tupno of result set dbres is NULL; false otherwise.

getdynfield dbres fno tupno] returns the value of field number fno in tuple tupno of result set dbres as a dynval (a wrapped value).

A NULL value is returned as will/Nal. Note that the partial application (getdynfield dbres fno) precomputes the type of the field fno. Hence it is far more efficient to compute let val getfno = getdynfield dbres fno in tabulate(ntuples dbres, getfno) end than to compute or tupno tupno = getdynfield dbres fno tupno in tabulate(ntuples dbres, getfno) end because the latter repeatedly computes the type of the field.

(getdyntup dbres tupno) returns the fields of tuple tupno in result set dbres as a vector of dynvals.

[getdyntups dbres] returns all tuples of result set dbres as a vector of vectors of dynvals.

[dynval2s dv] returns a string representing the dynval dv.

[applyto x f] computes f(x). This is convenient for applying several functions (given in a list or vector) to the same value: map (applyto 5) (tabulate(3, getdynfield dbres))

[getdynfield dbres 0 5, getdynfield dbres 1 5, getdynfield dbres 2 5] equals

[copytableto(dbconn, tablename, put)] executes a "COPY TABLE TO" statement, applies the function put to every tuple of the table, represented as a line of text (not terminated by newline \(\text{L})\), and cleans up at the end. For instance, to copy the contents of a table t to a text stream s (one tuple on each line), define

(TextIO.output(s, line); TextIO.output(s, "\n")) fun put line =

copytableto(dbconn, "t", put). and execute

[copytablefrom(dbconn, tablename, useput)] executes a "COPY TABLE FROM" statement, creates a put if function for copying lines to the table, passes the put function to useput, and cleans up at the end. The put function may be called multiple times for each line (tuple); the end of each line is indicated with the newline character "\n" as usual. For instance, to copy the contents of a text stream s to a table t, define

while not (TextIO.endOfStream s) do put(TextIO.inputLine s); fun useput put = and execute

copytablefrom(dbconn, "t", useput). Note that TextIO.inputLine preserves the newline at the end of each

[formattable dbresult] returns a wseg representing an HTML table. The HTML table has a column for every field in the dbresult. The dbresult at table header giving the names of the fields in the dbresult. The remaining rows correspond to the tuples in the dbresult, in the order they are provided by the database server. Null fields are shown as NULL.

[showquery dbconn query] sends the SQL query to the database server, then uses formattable to format the result of the query.

101

# Module Process

OS. Process -- SML Basis Library

eqtype status

: status : status val success val failure

: string -> status val system : (unit -> unit) -> unit val atExit

val exit : status -> 'a
val terminate : status -> 'a

: string -> string option val getEnv Portable functions for manipulating processes

[success] is the unique status value that signifies successful termination of a process. Note: MS DOS (sometimes) believes that all processes are successful.

[failure] is a status value that signifies an error during execution of a process. Note that in contrast to the success value, there may be several distinct failure values.

[system cmd] asks the operating system to execute command cmd, and returns a status value.

[atExit act] registers the action act to be executed when the current SML program calls Process.exit. Actions will be executed in reverse order of registration.

[exit i] executes all registered actions, then terminates the SML process with completion code i.

[terminate i] terminates the SML process with completion code i (but without executing the registered actions).

[getEnv evar] returns SOME s if the environment variable evar is defined and is associated with the string s; otherwise NONE.

102 RANDOM

# **Module Random**

```
Random -- random number generator

type generator
val newgenseed : real -> generator
val newgen : unit -> generator
val random : generator -> real
val randomlist : int * generator -> real
val randomlist : int * int -> generator -> int
val rangelist : int * int -> int * generator -> int
```

```
[generator] is the type of random number generators, here the linear congruential generators from Paulson 1991, 1996.

[newgenseed seed] returns a random number generator with the given seed. Intervent of the system clock.

[random gen] returns a random number in the interval [0..1).

[random gen] returns a random number in the interval [0..1).

[random list (m, gen)] returns a list of n random numbers in the interval [0,1).

[range (min, max) gen] returns an integral random number in the range [min, max). Raises Fail if min > max.

[rangelist (min, max) (n, gen)] returns a list of n integral random numbers in the range [min, max). Raises Fail if min > max.
```

REAL 103

#### Module Real

```
Real -- SML Basis Library
type real = real
```

[fromInt i] is the floating-point number representing integer i.

REAL 5

[floor r] is the largest integer <= r (rounds towards minus infinity). May raise Overflow.

[ceil r] is the smallest integer >= r (rounds towards plus infinity). May raise Overflow.

(trunc r] is the numerically largest integer between r and zero (rounds towards zero). May raise Overflow.

[round  $r\,]$  is the integer nearest to  $r\,,$  using the default rounding mode. May raise Overflow.

 $[=(x,\ y)]$  is equivalent to x=y in Moscow ML (because of the absence of NaNs and Infs).

 $[i=(x,\ \gamma)]$  is equivalent to x<>y in Moscow ML (because of the absence of NaNs and Infs).

 $[?=(x,\ y)]$  is false in Moscow ML (because of the absence of NaNs and Infs).

[fmt spec r] returns a string representing r, in the format specified by spec (see below). The requested number of digits must be >= 0 in the SCI and FIX formats and > 0 in the GNB format, otherwise Size is raised, even in a partial application fmt(spec).

C printf	t %e	t %.ne				s %.ng
	digits after point	gits after poin	gits after poin	digits after poin	significant digit	significant digit
-	9	Ц	9	ц	12	Д
description	scientific,	scientific,	fixed-point	fixed-point,	auto choice	auto choice
į		'n		ū		'n
	NONE	(SOME	NONE	(SOME	_	(SOME
spec	SCI	SCI	FIX	FIX	GEN	GEN

[toString r] returns a string representing r, with automatic choice of format according to the magnitude of r. Equivalent to (fmt (GEN NONE) r). [fromString s] returns SOWE(r) if a floating-point numeral can be scanned from a prefix of string s, ignoring any initial whitespace; returns NONE otherwise. The valid forms of floating-point numerals

are described by:  $[+ - -1?(([0-9]+()\cdot[0-9]+)?) \mid ((\cdot.[0-9]+)) \mid ([eE][+ - -1?[0-9]+)?$ 

[scan getc charsrc] attempts to scan a floating-point number from the character source charsrc, using the accessor getc, and ignoring any initial whitespace. If successful, it returns SOME(r, rest) where r is the number scanned, and rest is the unused part of the character source. The valid forms of floating-point numerals are described by:

[+~-]?(([0-9]+(\.[0-9]+)?)|(\.[0-9]+))([eE][+~-]?[0-9]+)?

Module Regex

REGEX

Regex -- regular expressions a la POSIX 1003.2 -- requires Dynlib

105

exception Regex of string

compiled regular expression type regex

Treat \n in target string as new line Compile POSIX extended RES Compile case-insensitive match datatype cflag Extended Newline Icase

datatype eflag Notbol

Do not match ^ at beginning of string Do not match \$ at end of string : string -> cflag list -> regex val regcomp Noteo1

: regex -> eflag list -> string -> substring vector option : regex -> eflag list -> string -> bool regexecBool val regexec

: regex -> eflag list -> substring val regnexec

-> substring vector option : regex -> eflag list -> substring -> bool val regnexecBool val regmatch
.> falag list -> substring } -> oflag list
-> falag list -> substring vector option
val regmatchBool : { pat : string, tgt : string } } -> oflag list
-> eflag list -> bool

datatype replacer = Str of string | Sus of int

A literal string The i'th parenthesized group Transformation of i'th group Tr of (string -> string) \* int

Transformation of all groups : regex -> replacer list -> string -> string : regex -> replacer list -> string -> string Trs of substring vector -> string replacel val val

: regex -> (string -> string) -> string -> string : regex -> (string -> string) -> string -> string val substitutel replace

: regex -> string -> substring list : regex -> string -> substring list tokens fields val

: regex -> (substring vector -> 'a) -> string -> 'a list regex -> (substring vector -> unit) -> string -> unit app fold map val val

-> (substring \* 'a -> 'a) \* (substring vector \* 'a -> 'a) -> 'a -> string -> 'a regex

This structure provides pattern matching with POSIX 1003.2 regular expressions. The form and meaning of Extended and Basic regular expressions are described below. Here R and S denote regular expressions; m and n denote natural numbers; L denotes a character list; and d denotes a decimal digit:

Match R zero or more times
Match R one or more times
Match R or S
Match R or the empty string
Match R exactly m times
Match R at least m times Match the character c Match any character Meaning R\* R/+ R/? R/? R/? R/{m,\} Basic Extended R{m} 공 장 U

```
Match R at least m and at most n times
   R\{m,n\}
[L]
[^L]
             $
+/\d
+/\d
```

Some example character lists L:

```
Match vowel: a or e or i or o or u
Match digit: 0 or 1 or 2 or ... or 9
Match non-digit
Match - or + or * or / or *
Match lowercase letter or hyphen (-)
Match letter or digit
Match letter or digit
Match letter or digit: same as [0-9]
Same as [:print:] but not [:space:]
Match printable character
Match printable digit; same as [0-9]
Match printable diaracter
Match buppercase letter
Match uppercase letter
Match uppercase Danish letters (ISO Latin 1)
                                                                                                                                                                                                                                                                                                                                                                                                                                              [:lower:]æøå]
                                                                                                       [-a-z]
[0-9a-fA-F]
                                                                                                                                                                                                                                                                                                                                                                                                                     [:xdigit:]
                                                                                                                                                                                                            [:cntr]:]
[:digit:]]
[:graph:]]
[:power:]]
[:print:]]
[:space:]]
                                                                                                                                                           [:alnum:]
[:alpha:]
                                                                                                                                                                                                                                                                                                                                                                                             [:upper:]
          [aeiou]
[0-9]
[^0-9]
[-+*/^]
```

Remember that backslash (\) must be escaped as "\\" in SML strings.

[regcomp pat cflags] returns a compiled representation of the regular expression pat. Raises Regex in case of failure. cflag] is the type of compilation flags with the following meanings:

```
[Extended] : compile as POSIX extended regular expression.
[Icase] : compile case-insensitive match.
[Newline] : make the newline character 'n significant, so ^ matches just after newline (\n'), and $ matches just before \n.
```

Example: Match SML integer constant: regcomp "^~?[0-9]+\$" [Extended] Example: Match SML alphanumeric identifier: regcomp "^[a-zA-Z0-9][a-zA-Z0-9'\_]\*\$" [Extended]

Example: Match SML floating-point constant: regcomp "^[+-]?[0-9]+(\\.[0-9]+(\\.[0-9]+)?[eE][+-]?[0-9]+)\$" [Extended]

Example: Match any HTML start tag; make the tag's name into a group: regcomp "<([[:alnum:]]+)[^>]\*>" [Extended]

[regexec regex eflags s] returns SOME(vec) if some substring of smatches regex, NONE otherwise. In case of success, vec is the match vector, a vector of substrings such that vec[0] is the (longest leftmos!) substring of smatching regex, and vec[1], vec[2], ... are substrings matching the parenthesized groups in pat (numbered 1, 2, ... from left to right in the order of their opening parenthese). For a group that does not take part in the match, such as (ab) in "(ab)|(cd)" when matched against the string "xcdy", the corresponding substring is the empty substring at the despinning of the underlying string. For a group that trakes part in the match repeatedly, such as the group (b+) in "(a(b+))\*" when matched against "babbabbb", the corresponding substring is the last rightmost) one

eflag] is the type of end flags with the following meaning;

Notbol] : do not match ^ at beginning of string

REGEX

[Noteol] : do not match \$ at end of string.

107

regexecBool regex eflags s] returns true if some substring of s matches regex, false otherwise. Equivalent to, but faster than, Option.isSome(regexec regexec eflags s).

[regnexec regex eflags sus] returns SOME(vec) if some substring of sus matches regex, NONE otherwise. The substrings returned in the vector vec will have the base string as sus. Useful e.g. for splitting a string into fragments separated by substrings matching some regular expression. [regnexecDool regex eflags sus] returns true if some substring of sus matches regex, false otherwise. Equivalent to, but faster than, Option.isSome(regnexec regexec eflags sus).

but more efficient when the compiled regex is used only once. regmatch { pat, tgt } cflags eflags] is equivalent to regexec (regcomp pat cflags) eflags tgt

[replace regex repl s] finds the (disjoint) substrings of s matching regex from left to right, and returns the string obtained from s by applying the replacer list repl to every such substring decomposing s, that is, if regex matches an empty string at the head of s or immediately after a previous regex match. Example use: delete all HTML tags from s: replace (regcomp "<[^>]+>" [Extended]) [] s

[replace1 regex repl s] finds the leftmost substring bl of s matching regex, and returns the string resulting from s by applying the replacer list repl to the match vector vecl (see below)

Let x0 be a substring matching the entire regex and xi be the substring matching the i'th parenthesized group in regex; thus xi vec[i] where vec is the match vector (see regexec above). Then a single replacer evaluates to a string as follows:

f (vec) f(xi) gives the string s gives the string x gives the string f gives the string f [Str s] [Sus i] [Tr (f, i)] [Trs f] A replacer list repl evaluates to the concatenation of the results The replacers are applied from left to right. of the replacers.

bn Equivalent [substitute regex f s] finds the (disjoint) substrings bl, ..., of s matching regex from left to right, and returns the string obtained from s by replacing every bi by (ful). Function f is applied to the matching substrings from left to right. Raises Regex if it fails to make progress in decomposing s. Equivalen replace regex [Tr (f, 0)] s

s replacing [substitute] regex f s] finds the leftmost substring b of matching regex, and returns the string obtained from s by that substring by f(b). Equivalent to replace1 regex [Tr (f, 0)] s [map regex f s] finds the (disjoint) substrings of s matching regex from left to right, applies f to the match vectors vecl, ..., veen, and returns the list [fivecl). ..., f(vecn)]. Raises Regex if it falls to make progress in decomposing s.

(app regex f s] finds the (disjoint) substrings of s matching regex from left to right, and applies f to the match vectors vecl, ..., vecn. Raises Regex if the regex fails to make progress in decomposing s.

```
(fold regex (op ::, fapp (Substring.all o f o get 0)) [] s))
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Two tokens may be separated by more than one delimiter, whereas two fields are separated by exactly one delimiter. If the only delimiter is the character #" ", then "abc||def contains three fields: "abc" and "a and "def"
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           [fold regex (fa, fb) e s] finds the (disjoint) substrings bl, ..., bu of s matching regex from left to right, and splits s into the substrings at a0, bl, al, b2, a2, ..., bn, an where n = 0 and where a0 is the (possibly empty) substring of spreeding the first match, and ai is the (possibly empty) substring between the matches bi and b(i+1). Then it computes and returns falan, fb(vecn, ..., fa(al, fb(vecl, ra(alo, e))) ...)) where veci is the match vector corresponding to bi. Raises Regex if it fails to make progress in decomposing s.
                                                                                                                                                                                                                                                                                                                                                                        [tokens regex s] returns the list of tokens in s, from left to right. A token is a non-empty maximal substring of s not containing any delimiter. A delimiter is a maximal substring that matches regex. The eliags Notbol and Noteol are set. Raises Regex if it fails to make progress in decomposing s. Equivalent to List.filter (not o Substring.isEmpty) (fields regex s)
[fields regex s] returns the list of fields in s, from left to right. A field is a (possibly empty) maximal substring of s not containing any delimiter. A delimiter is a maximal substring that matches regex. The eflags Notbol and Noteol are set. Raises Regex if it fails to make progress in decomposing s.

Example use:
fields (regcomp " *; *" []) "56; 23; 22;; 89; 99"
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    map regex f s = List.rev (fold regex (#2, fapp f) [] s)

val titi : signal
val ttiti : signal

val toWord : signal -> Word.word val fromWord : Word.word -> signal

[signal] is the type of  $\mathrm{Unix/Posix\text{--}style}$  signals, which can be sent to another process.

[toWord sig] returns the signal number as an unsigned word.

[fromWord w] returns the signal whose number is w.

[abrt] is SIGABRT, the abort signal from abort(3).

[alrm] is SIGALRM, a timer signal from alarm(1).

[bus] is SIGBUS, a bus error.

[fpe] is SIGFPE, a floating point exception.

[hup] is SIGHUP, a hangup.

[ill] is SIGILL, an illegal instruction.

[int] is SIGINT, an interrupt.

[kill] is SIGKILL, the kill signal.

[pipe] is SIGPIPE, a broken pipe.

[quit] is SIGQUIT, a quit from keyboard.

[segv] is SIGSEGV, a segmentation violation.

[usr1] is SIGUSR1, the first user signal.

[term] is SIGTERM, the termination signal.

usr2] is SIGUSR2, the second user signal.

[chld] is SIGCHLD, child process stopped or terminated.

[cont] is SIGCONT, continue if stopped.

[stop] is SIGSTOP, signal to stop process.

[tstp] is SIGTSTP, a stop signal typed at the tty.

111

[ttin] is SIGTTIN, tty input for background process.

[ttou] is SIGTIOU, tty output for background process.

# Module Socket

```
The Unix file protocol family The Internet protocol family
                                                                                                                                                                      A stream socket
A passive stream
An active, connected, stream
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         -> { rds : sock_desc list, wrs : sock_desc list, exs : sock_desc list

Structure Socket defines functions for creating and using sockets, a means for communication between SML processes on the same machine or via a network.

[('addressfam, 'socktype) sock] is the type of sockets with address family 'addressfam and having type 'socktype.

('addressfam sock\_addr] is the type of sockets addresses

The possible address (protocol) families are

active, or connected, stream sockets The Unix address family (file) The Internet address family stream sockets passive stream sockets datagram sockets possible socket types are type 'a stream type passive type pf\_file type pf\_inet type active type dgram The

[fileAddr fname] returns a socket address for the Unix protocol family, created from the given file name fname.

[inetAddr inetaddr portno] returns a socket address for the Internet protocol family, created from the given Internet number (e.g. "130.225.40.253") and port number (e.g. 8080).

fileStream ()] returns a new stream socket for the Unix protocol

fileDgram ()] returns a new datagram socket for the Unix protocol [inetStream ()] returns a new stream socket for the Internet protocol family. [amily

[inetDgram ()] returns a new datagram socket for the Internet protocol family.

[accept sock] extracts the first connection on the queue of pending connections to sock. Returns (sock, adar) where sock is a copy of the socket sock, bound to that connection, and adar is the address of the communications counterpart (the other end of the connection). Blocks if no connections are pending. The stream socket sock must have been assigned a name (with bind) and must be listening for connections (following a call to listen).

[bind sock addr] binds the socket sock to the address addr, that is, assigns the name addr to the socket. Binding a name in the

114 SOCKET

Unix protocol family creates a socket in the file system that must be deleted when it is no longer needed [connect (sock, addr)] attempts to connect socket sock to the communications peer at address addr. If sock is a datagram socket, then addr is the address to which datagrams is to be sent, and the only address from which datagrams will be accepted. If sock is a stream socket, then addr specifies another socket to which to connect.

[listen (sock, queuelen)] enables the passive stream socket sock to accept incoming connections. The parameter queuelen specifies the maximal number of pending connections. Further connections from clients may be refised when this limit is reached.

close sock] closes the socket.

[shutdown sock shutdown\_mode] shuts down socket sock for further communication, as specified by the shutdown\_mode parameter:

NO\_RECVS] no further receives are allowed;

[NO\_SENDS] no further sends are allowed;

[NO\_RECUS\_OR\_SENDS] no further receives or sends are allowed.

getinetaddr addr] returns the Internet number (e.g. "130.225.40.253") of the Internet socket address addr.

['a buf] is the type of records { buf, ofs, size } which represent subvectors or subarrays:
if size = SOME s it represents buf[ofs..ofs+s-1];
if size = NOME it represents buf[ofs..len-1] where len is buf's length.
Mhen the subbuffer is used in a call, exception Subscript will be raised if ofs < 0 or size < 0 or ofs+size > len.

[sendVec (sock, vecbuf)] transmits the bytes from buffer vecbuf on the active stream socket sock. Returns the number of bytes sent. Blocks until sufficient space is available at the socket.

sendArr (sock, arrbuf)] is analogous til sendVec.

[sendVec' (sock, vecbuf, out\_flags)] transmits the bytes from buffer vecbuf on the active stream socket sock, observing the out\_flags. Returns the number of bytes sent. Blocks until sufficient space is available at the socket.

[out\_flags] is the type of records { don't\_route, oob } in which the field don't\_route specifies whether routing should be bypassed, and the field oob specifies whether data should be sent out-of-band

sendArr' (sock, arrbuf, out\_flags)] is analogous til sendVec'.

[sendyecTo (sock, addr, vecbuf)] transmits the bytes from buffer vecbuf on the datagram socket sock to the target address addr. Returns the number of bytes sent. Blocks until sufficient space is available at the socket.

sendArrTo (sock, addr, arrbuf)] is analogous til sendVecTo.

[sendVecTo' (sock, addr, vecbuf, out\_flags)] transmits the bytes from buffer vecbuf on the datagram socket sock to the target address addr, observing the out\_flags. Returns the number of bytes sent. Blocks until sufficient space is available at the socket. See above for a description of vecbuf and out\_flags.

sendArrTo' (sock, addr, arrbuf, out\_flags)] is analogous til sendVecTo'.

[recvVec (sock, n)] receives up to n bytes from the active stream socket sock. Returns a byte vector containing the bytes actually received. Blocks until some additate become available at the socket, then returns any available data, up to n bytes. Excess data are

SOCKET

115

not lost; they are available for subsequent receive calls.

[recvArr (sock, arrbuf)] receives bytes from the active stream socket sock into the subarray arrbuf, up to the available space. If #size(arrbuf) = SOME(s) the available space is bytes; if #size(arrbuf) = NONE the available space is len - #ofs(arrbuf) bytes. Returns the number of bytes actually received. Blocks until some data become available at the socket. Excess data are not lost; they are available for subsequent receive calls.

[recvVec' (sock, n, in\_flags)] receives up to n bytes from the active stream socket sock, observing the in\_flags. Returns a byte vector containing the bytes actually received. Blocks until some data become available at the socket, then returns any available data, up to n bytes. Data in excess of n bytes are not lost; they are available for subsequent receive calls.

[in\_flags] is the type of records { peek, oob } in which the field peek specifies that the data read should not be removed from the receive queue, and the field oob specifies that data may be received out-of-band.

[recvArr' (sock, arrbuf, in\_flags)] receives bytes from the active stream socket sock into the subarray arrbuf, observing the in\_flags, up to the available space. Returns the number of bytes actually received. Blocks until some data become available at the subsequent receive calls.

[recvVecFrom (sock, n)] receives up to n bytes from the datagram socket sock. Returns a byte vector containing the bytes actually received. Blocks until some data become available at the socket, then returns any available data, up to n bytes.

[recvArrFrom (sock, arrbuf)] receives bytes from the datagram socket sock into the subarray arrbuf. Returns the number of bytes actually received. Blocks until some data become available at the

[recvVecFrom' (sock, n, in\_flags)] receives up to n bytes from the datagram socket sock, observing the in\_flags (see above). Returns (vec, addr) where vec is a byte vector containing the bytes actually received, and addr is the source address of the message. Blocks until some data become available at the socket, then returns any available data, up to n bytes.

[recvArrFrom' (sock, arrbuf, in\_flags)] receives bytes from the datagram socket sock into the array buffer arrbuf, observing the in\_flags (see above). Returns (n, addr) where n is the number of bytes actually received, and addr is the source address of the message. Blocks until some data become available at the socket.

[sockDesc sock] returns a descriptor for the socket sock, to be used in a call to select.

[compare (sdl, sd2)] compares sdl and sd2 according to an unspecified total ordering, and returns LESS if sdl precedes sd2, returns GREATER is sdl precedes sd2, and returns EQUAL otherwise.

sameDesc (sdl, sd2)] returns true if sdl and sd2 describe the same socket. Equivalent to compare(sdl, sd2) = EQUAL.

[select { rds, wrs, exs, timeout }] blocks the calling process until some input/output operations become possible on some sockets. The call will check the sockets described in rds for reading, those in wrs for writing, and those in exs for exceptional conditions. Feturns { rds, wrs, exs } where rds now is a list of descriptors of sockets ready for writing, and exceptional conditions. The order of the socket descriptors in the results is the same as their order in the corresponding arguments. If timeout is NOWE then the call blocks until some input/output operations become possible; if timeout is SOWE(t) then the call

J16 St

blocks for at most time t.

A server socket is considered ready for reading if there is a pending connection which can be accepted with 'accept'. A client socket is ready for writing when its connection is fully established.

SPLAYMAP

Module Splaymap

117

Splaymap -- applicative maps implemented by splay-trees From SML/NJ lib 0.2, copyright 1993 by AT&T Bell Laboratories

val transform : ('a -> '\_b) -> 'c' key, 'a) dict -> 'b) dict

[('key, 'a) dict] is the type of applicative maps from domain type 'key to range type 'a, or equivalently, applicative dictionaries with keys of type 'key and values of type 'a. They are implemented as ordered splay-trees (Sleator and Tarjan).

[mkDict ordr] returns a new, empty map whose keys have ordering

[insert(m, i, v)] extends (or modifies) map m to map i to v.

[find (m, k)] returns v if m maps k to v; otherwise raises NotFound.

[peek(m, k)] returns SOME v if m maps k to v; otherwise returns NONE. [remove(m, k)] removes k from the domain of m and returns the modified map and the element v corresponding to k. Raises NotFound if k is not in the domain of m.

[numItems  $m \, ]$  returns the number of entries in m (that is, the size of the domain of  $m \, ).$ 

[listItems m] returns a list of the entries (k, v) of keys k and the corresponding values v in m, in increasing order of k. [app f m] applies function f to the entries (k, v) in m, in increasing order of k (according to the ordering ordr used to create the map or dictionary).

[revapp f m] applies function f to the entries  $(k,\ v)$  in m, in decreasing order of k.

[fold] f e m] applies the folding function f to the entries  $(k,\ v)$  in m, in increasing order of k.

[foldr f e m] applies the folding function f to the entries  $(k,\;v)$  in m, in decreasing order of k. [map f m] returns a new map whose entries have form  $(k,\;f(k,v))$ , where  $(k,\;v)$  is an entry in m.

[transform f m] returns a new map whose entries have form (k, f v), where (k, v) is an entry in m.

SPLAYSE

# Module Splayset

118

Splayset -- applicative sets implemented by splay-trees From SML/NJ lib 0.2, copyright 1993 by AT&T Bell Laboratories

type 'item set

exception NotFound

['item set] is the type of sets of ordered elements of type 'item. The ordering relation on the elements is used in the representation of the set. The result of combining two sets with different underlying ordering relations is undefined. The implementation uses splay-trees (Sleator and Tarjan).

empty ordr] creates a new empty set with the given ordering

[singleton ordr i] creates the singleton set containing i, with the given ordering relation.

[add(s, i)] adds item i to set s.

[addList(s, xs)] adds all items from the list xs to the set s.

[retrieve(s, i)] returns i if it is in s; raises NotFound otherwise.

[peek(s, i)] returns SOME i if i is in s; returns NONE otherwise.

[isEmpty s] returns true if and only if the set is empty.

same elements.

[equal(s1, s2)] returns true if and only if the two sets have the

isSubset(s1, s2)] returns true if and only if s1 is a subset of s2.

[member(s, i)] returns true if and only if i is in s.

delete(s, i)] removes item i from s. Raises NotFound if i is not in s.

numItems s] returns the number of items in set s.

union(s1, s2)] returns the union of s1 and s2.

intersection(s1, s2)] returns the intersectionof s1 and s2.

[difference(s1, s2)] returns the difference between s1 and s2 (that is, the set of elements in s1 but not in s2).

SPLAYSET

119

[listItems s] returns a list of the items in set s, in increasing order.

lapp f s] applies function f to the elements of s, in increasing
order.
[revapp f s] applies function f to the elements of s, in decreasing

order. [fold] f e s] applies the folding function f to the entries of the set in increasing order.

folds f e slapples the folding function f to the entries of the set in decreasing order.

set in decreasing order. [find p s] returns SOWE i, where i is an item in s which satisfies p, if one exists; otherwise returns NOME.

```

Pud

returns the string consisting of the resulting characters and

121

CharVector.map f s implode (List.map f (explode s)). Equivalent to

ಭ [translate f s] applies f to every character of s, from left tright, and returns the concatenation of the resulting strings. Raises Size if the sum of their sizes is greater than maxSize. Equivalent to concat (List.map f (explode s)). (tokens p s] returns the list of tokens in s, from left to right, where a token is a non-empty maximal substring of s not containing any delimiter, and a delimiter is a character satisfying p.

[fields p s] returns the list of fields in s, from left to right, where a field is a (possibly empty) maximal substring of s not containing any delimiter, and a delimiter is a character satisfying ;

Two tokens may be separated by more than one delimiter, whereas two fields are separated by exactly one delimiter. If the only delimiter is the character #", then ", then "abc | |def contains two tokens: "abc" and "def"

"abc||def" contains three fields: "abc" and "" and "def" [isprefix s1 s2] is true if s1 is a prefix of s2. That is, if there exists a string t such that s1  $^{\circ}$  t = s2. [fromString s] scans the string s as an ML source program string, converting escape sequences into the appropriate characters. Does not skip leading whitespace.

[toString s] returns a string corresponding to s, with non-printable characters replaced by ML escape sequences. Equivalent to String.translate Char.toString.

[fromCString s] scans the string s as a C source program string, converting escape sequences into the appropriate characters. Do not skip leading whitespace

[toCString s] returns a string corresponding to s, with non-printable characters replaced by C escape sequences. Equivalent to String.translate Char.toCString.

[compare (sl, s2)] does lexicographic comparison, using the standard ordering Char.compare on the characters. Returns LESS, EQUAL, or GREATER, according as sl is less than, equal to, or greater than s2. [collate cmp (s1, s2)] performs lexicographic comparison, using the given ordering cmp on characters.

⊽, ,

str c] is the string of size one which contains the character c.

 $\ensuremath{\text{cs}}\xspace$  is the string containing the characters in the list of to concat (List.map str  $\ensuremath{\text{cs}}\xspace).$ 

quivalent to implode

[map f s] applies f to every character of s, from left to right,

explode s] is the list of characters in the string s.

[>=] compare strings lexicographically, using the representation ordering on characters.

```

This structure presents tools for scanning strings and values from functional character streams, and for simple formatting.

[('elm, 'src) reader] is the type of source readers for reading a sequence of 'elm values from a source of type 'src. For instance, a character source reader getc: (char, reader getc: (char, res) reader is used for obtaining characters from a functional character source src of type cs, one at a time. It should hold that getc src = SOME(c, src') if the next character in src is c, and src' is the rest of src; if src contains no characters

A character source scanner takes a character source reader getc as argument and uses it to scan a data value from the character

[scanString scan s] turns the string s into a character source and applies the scanner 'scan' to that source.

[split] p getc src] returns (pref, suff) where pref is the longest prefix (left substring) of src all of whose characters satisfy p, and suff is the remainder of src. That is, the first character retrievable from suff, if any, is the leftmost character not satisfying p. Does not skip leading whitespace.

[takel p getc src] returns the longest prefix (left substring) of src all of whose characters satisfy predicate p. That is, if the left-most character does not satisfy p, the result is the empty string. Does not skip leading whitespace. It holds that takel p getc src = #1 (split1 p getc src)

[drop] p getc src] drops the longest prefix (left substring) of src all of whose characters satisfy predicate p. If all characters do, it returns the empty source. It holds that drop] p getc src = #2 (split] p getc src)

[skipWS getc src] drops any leading whitespace from src. Equivalent to drop1 Char.isSpace. [padLeft c n s] returns the string s if size s >= n, otherwise pads s with (n - size s) copies of the character c on the left. In other words, right-justifies s in a field n characters wide.

STRINGCVT

123

[padRight c n s] returns the string s if size s >= n, otherwise pads s with (n - size s) copies of the character c on the right. In other words, left-justifies s in a field n characters wide.

124 SUBSTRII

125

[isEmpty (s, i, n)] true if the substring is empty (that is, n = 0)

[base sus] is the concrete triple (s, i, n), where sus = (s, i, n).

SUBSTRING

# Module Substring

```
int -> substring -> substring
int -> substring -> substring
int -> char
substring -> int -> char
substring -> int -> char
substring -> int int option -> substring
substring int * int option -> substring
substring list -> string
substring | string -> char list
string -> substring -> order
substring * substring -> order
(char * char -> order) -> substring -> order
                                                                                                                                                                                                                                                                                                                                                                                                                                              -> bool) -> substring -> substring
-> bool) -> substring -> substring * substring
-> bool) -> substring -> substring * substring

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 val
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 val
```

[substring] is the type of substrings of a basestring, an efficient representation of a piece of a string.

A substring (s,i,n) is valid if 0 <= i <= i+n <= size s,

A valid substring (s,i,n) represents the string sli...i+n-1].

Invariant in the implementation: Any value of type substring is valid.

[substring (s,i,n)] creates the substring sli...i+n-1].

[substring (s,i,n)] creates the substring (s,i,n), consisting of the substring of s with length n starting at i. Raises Subscript if ico or nc0 or i+n > size s. Equivalent to extract(s,i, SOWE n).

[extract(s,i,NONE)] creates the substring (s,i,size s-i) consisting of the tail of s starting at i.

Raises Subscript if ico or i > size s.

[extract(s,i,SOWE n)] creates the substring (s,i,n),

consisting of the substring of s with length n starting at i.

Raises Subscript if ico or nco or i+n > size s.

[all s] is the substring (s, 0, size s).

[string sus] is the string s[i.i+n-1] represented by sus = (s,i,n).

[taker p sus] returns the longest suffix (right substring) of sus all of whose characters satisfy predicate p. That is, if the right-most character satisfies p, returns the empty (s, i+n, 0)

Let p be a predicate and xxxxfyyyyfzzzz a string where all

where sus = (s, i, n).

[takel p sus] returns the longest prefix (left substring) of sus all of whose characters satisfy predicate p. That is, if the left-most character does not satisfy p, returns the empty  $(s,\ i,\ where\ sus\ =\ (s,\ i,\ n)$ .

[collate cmp (sus1, sus2)] performs lexicographic comparison, using the given ordering cmp on characters. Equivalent to, but more efficient than, String.collate cmp (string sus1, string sus2). [trimr k sus] returns sus less its rightmost k characters; or the empty string at the beginning of sus if it has less than k characters. Raises Subscript if k < 0, even in the partial application triml(k). [slice (sus, i', SOME n')] returns the substring (s, i+i', n'), where sus = (s, i, n). Raises Subscript if i' < 0 or n' < 0 or i'+n' >= n. [slice (sus, i', NONE)] returns the substring (s, i+i', n-i'), where sus = (s, i, n). Raises Subscript if i' < 0 or i' > n. [concat suss] returns a string consisting of the concatenation of the substrings. Equivalent to String.concat (List.map string suss). [trim] k sus] returns sus less its leftmost k characters; or the empty string at the end of sus if it has less than k characters. Raises Subscript if k < 0, even in the partial application trim](k). sub (sus, k)] returns the k'th character of the substring; that is, [isPrefix s1 s2] is true if s1 is a prefix of s2. That is, if there exists a string t such that string s1  $^{\wedge}$  t = string s2. [dropr p sus] drops the longest suffix (right substring) of sus all of whose characters satisfy predicate p. If all characters do, it returns the empty substring (s, i, 0) where sus = (s, i, n). compare (sus1, sus2)] performs lexicographic comparison, using the [dropl p sus] drops the longest prefix (left substring) of sus all of whose characters satisfy predicate p. If all characters do, it returns the empty substring (s, i+n, 0) where sus = (s, i, n). first character and sus] returns SOME c where c is the first character in sus, is non-empty; otherwise returns NONE. [getc sus] returns SOME(c, rst) where c is the first character arest the remainder of sus, if sus is non-empty; otherwise returns  $[s(i), s(i+1), \ldots, s(i+n-1)]$  where sus = (s, i, n). Equivalent to String.explode(string ss). standard ordering Char.compare on the characters. Returns LESS, EQUAL, or GRRATER, according as sual is less than, equal to, or greater than suals. Equivalent to, but more efficient than, String.compare(string sual, string sual). [size (s, i, n)] returns the size of the substring, that is, n. s(i+k) where sus = (s, i, n). Raises Subscript if k<0 or k>=n explode sus] returns the list of characters of sus, that is, is equivalent to, but more efficient than, valOf o StringCvt.scanString scanFn o Substring.string Note that #1 o valOf o scanFn Substring getc sus = (s, i, n). [first sif sus :

126 SUBSTRING

characters in xxxx and zzzz satisfy p, and f a is character not satisfying p. Then

sus = xxxxfyyyyfzzzz sus = xxxxzzzz dropl p sus = fyyyyfzzzz dropr p sus = xxxxfyyyf xzzz taker p sus = xzxx zzzz taker p sus = zzzz xxxxzzzz

It also holds that

concat[takel p sus, dropl p sus] = string sus concat[dropr p sus, taker p sus] = string sus [split1 p sus] splits sus into a pair (sus1, sus2) of substrings where sus1 is the longest prefix (left substring) all of whose characters satisfy p, and sus2 is the rest. That is, sus2 begins with the leftmost character not satisfying p. Disregarding sideeffects, we have.

split1 p sus = (takel p sus, dropl p sus).

[splitr p sus] splits sus into a pair (sus1, sus2) of substrings where sus2 is the longest suffix (right substring) all of whose characters satisfy p, and sus1 is the rest. That is, sus1 ends with the rightmost character not satisfying p. Disregarding sideeffects, we have:

splitr p sus = (dropr p sus, taker p sus)

[splitht (sus, k)] returns the pair (sus1, sus2) of substrings, where sus1 contains the first k characters of sus, and sus2 contains the rest. Raises Subscript if k < 0 or k > size sus.

[position s (s',i,n)] splits the substring into a pair (pref, suff) of substrings, where suff is the longest suffix of (s',i,n) which has s as a prefix. More precisely, let m=size s. If there is a least index k in i...i+n-m for which s=s'(k...km-1), then the result is pref = (s',i,k-1) and suff = (s',k,n-(k-i)); otherwise the result is pref = (s',i,n) and suff = (s',i+n,0).

[span (sus1, sus2)] returns a substring spanning from the start of sus1 is to the end of sus2, provided this is well-defined: sus1 and sus2 must have the same underlying string, and the start of sus1 must not be to the right of the end of sus2, otherwise raises Span.

More precisely, if base(sus1) = (s,i,n) and base(sus2) = (s',i',n') and s=s' and i=i'+n', then base(join(sus1, sus2)) = (s,i,i'+n'-i). This may be used to compute 'span', 'union', and 'intersection'.

[translate f sus] applies f to every character of sus, from left to right, and returns the concatenation of the results. Raises Size if the sum of their sizes is greater than String.maxSize. Equivalent to String.concat(List.map f (explode sus)).

[tokens p sus] returns the list of tokens in sus, from left to right, where a token is a non-empty maximal substring of sus not containing any delimiter, and a delimiter is a character satisfying p.

[fields p sus] returns the list of fields in sus, from left to right, where a field is a (possibly empty) maximal substring of sus not containing any delimiter, and a delimiter is a character satisfying p.

Two tokens may be separated by more than one delimiter, whereas two fields are separated by exactly one delimiter. If the only delimiter is the character # ", then "abc||def" contains two tokens: "abc" and "def"

"abc | def" contains three fields: "abc" and "" and "def" ldl f e sus] folds f over sus from left to right. That is,

[fold] f e sus] folds f over sus from left to right. That is, evaluates f[s[1+n-1], f( $\ldots$  f[s[1+1], f[s[1]  $\S$  e))  $\ldots$ )) Equi-recursively, where sus = (s, i, n), (n). Equi-valent to List.foldl f e (explode sus).

SUBSTRING

127

[foldr f e sus] folds f over sus from right to left. That is, evaluates f(s[i], f(s[i+1], f(...f(s[i+n-1] % e) ...))) tail-recursively, where sus = (s, i, n). Squivalent to List foldr f e (explode sus).

[app f sus] applies f to all characters of sus, from left to right. Equivalent to List.app f (explode sus).

SUSP128

#### Module Susp

```
Susp -- support for lazy evaluation
                                          type 'a susp
```

val delay : (unit -> 'a) -> 'a susp
val force : 'a susp -> 'a

[delay (fn () => e)] creates a suspension for the expression e. The first time the suspension is forced, the expression e will be evaluated, and the result stored in the suspension. All subsequent forcing of the suspension will just return this result, so e evaluated at most once. If the suspension is never forced, then e ['a susp] is the type of lazily evaluated expressions with result type 'a. is never evaluated.

[force su] forces the suspension su and returns the result of the expression e stored in the suspension.

type outstream

val openOut : string -> outstream
val openAppend : string -> outstream
val oloseOut : outstream -> unit
val output : outstream \* vector -> unit
val output : outstream \* elem -> unit
val outputSubstr : outstream \* subering -> unit
val flushOut : outstream \* substring -> unit
val flushOut : outstream -> unit

: outstream outstream val stdOut

: string -> unit val print This structure provides input/output functions on text streams. The functions are state-based: reading from or writing to a stream changes the state of the stream. The streams are buffered: output to a stream may not immediately affect the underlying file or device.

Ъ Note that under DOS, Windows, OS/2, and MacOS, text streams will 'translated' by converting (e.g.) the double newline CRLF to a single newline character \n.

[instream] is the type of state-based characters input streams.

[outstream] is the type of state-based character output streams

[elem] is the type char of characters.

[vector] is the type of character vectors, that is, strings

TEXT INPUT:

[openIn s] creates a new instream associated with the file named Raises Io. Io is file s does not exist or is not accessible.

[closeIn istr] closes stream istr. Has no effect if istr is closed

TEXTIO 130

at 13 Further operations on istr will behave as if istr end of stream (that is, will return "" or NONE or true). [input istr] reads some elements from istr, returning a vector v of those elements. The vector will be empty (size v = 0) if and only if istr is at end of stream or is closed. May block (not return until data are available in the external world).

[inputAll istr] reads and returns the string v of all characters remaining in istr up to end of stream.

[inputNoBlock istr] returns SOME(v) if some elements v can be read without blocking; returns SOME("") if it can be determined without blocking that istr is at end of stream; returns NOME otherwise. If istr does not support non-blocking input, raises
Io.NomblockingNotSupported.

[imputl istr] returns SOWE(e) if at least one element e of istr is available; returns NONE if istr is at end of stream or is closed; blocks if necessary until one of these conditions holds.

[inputN(istr, n)] returns the next n characters from istr as a string, if that many are available; returns all remaining characters if end of stream is reached before n characters are available; blocks if necessary until one of these conditions holds. (This is the behaviour of the 'input' function prescribed in the 1990 Definition of Standard ML).

[inputLine istr] returns one line of text, including the terminating newline character. If end of stream is reached before a newline character, then the remaining part of the stream is returned, with a newline character added. If istr is at end of stream or is closed, then the empty string "" is returned. [endOfStream istr] returns false if any elements are available in istr; returns true if istr is at end of stream or closed; blocks if necessary until one of these conditions holds.

[lookahead istr] returns SOME(e) where e is the next element in the stream; returns NONE if istr is at end of stream or is closed; blocks if necessary until one of these conditions holds. Does not advance the stream.

stdIn] is the buffered state-based standard input stream.

[soanStream scan istr] turns the instream istr into a character source and applies the scanner 'scan' to that source. See Stringovt for more on character sources and scanners. The Moscow ML implementation currently can backtrack only 512 characters, and raises Fail if the scanner backtracks further than that.

#### TEXT OUTPUT:

[openOut s] creates a new outstream associated with the file named s. If file s does not exist, and the directory exists and is writable, then a new file is created. If file s exists, it is truncated (any existing contents are lost).

13 [openAppend s] creates a new outstream associated with the file named s. If file s does not exist, and the directory exists and writable, then a new file is created. If file s exists, any existing contents are retained, and output goes at the end of the [closeOut ostr] closes stream ostr; further operations on ostr (except for additional close operations) will raise exception Io.Io.

output(ostr, v)] writes the string v on outstream ostr.

outputl(ostr, e)] writes the character e on outstream ostr.

TEXTIO

131

written to ostr becomes available to the underlying file or device. [flushOut ostr] flushes the outstream ostr, so that all data

[stdOut] is the buffered state-based standard output stream.

That [stdErr] is the unbuffered state-based standard error stream. Tiles, it is always kept flushed, so flushOut(stdErr) is redundant.

print s] outputs s to stdOut and flushes immediately

The functions below are not yet implemented:

[setPosIn(istr, i)] sets istr to the (untranslated) position i. Raises Io.Io if not supported on istr.

getPosIn istr] returns the (untranslated) current position of istr Raises Io. Io if not supported on istr.

[endPosIn istr] returns the (untranslated) last position of istr. Because of translation, one cannot expect to read endPosIn istr - getPosIn istr from the current position.

[getDosOut ostr] returns the current position in stream ostr. Raises Io.Io if not supported on ostr.

endPosOut ostr] returns the ending position in stream ostr. Raises Io.Io if not supported on ostr. setPosOut(ostr, i)] sets the current position in stream to ostr . Raises Io.Io if not supported on ostr.

2

mkInstream sistr] creates a state-based instream from the functional instream sistr. getInstream istr] returns the functional instream underlying the

state-based instream istr

setInstream(istr, sistr)] redirects istr, so that subsequent input is taken from the functional instream sistr.

the

the outstream sostr

mkOutstream sostr] creates a state-based outstream from

getOutstream ostr] returns the outstream underlying state-based outstream ostr. [setOutstream(ostr, sostr)] redirects the outstream ostr so that subsequent output goes to sostr.

val
```

[time] is a type for representing durations as well as absolute points in time (which can be thought of as durations since some fixed time zero). [zeroTime] represents the 0-second duration, and the origin of time, so zeroTime + t = t + zeroTime = t for all t.

[now ()] returns the point in time at which the application occurs. [fromSeconds s] returns the time value corresponding to s seconds. Raises Time if  $s\,<\,0\,.$ 

[fromMilliseconds ms] returns the time value corresponding to ms milliseconds. Raises Time if  $\ensuremath{\mathrm{ms}} < 0.$ 

[fromMicroseconds us] returns the time value corresponding to us microseconds. Raises Time if us  $<0\,.$ 

[toSeconds t] returns the number of seconds represented by t, truncated. Raises Overflow if that number is not representable as an int.

[toMilliseconds t] returns the number of milliseconds represented by t, truncated. Raises Overflow if that number is not representable as an int.

[toMicroseconds t] returns the number of microseconds represented by t, truncated. Raises Overflow if t that number is not representable as an int. [fromReal r] converts a real to a time value representing that many seconds. Raises Time if r < 0 or if r is not representable as a time value. It holds that realToTime 0.0 = zeroTime.

[toReal t] converts a time the number of seconds it represents;

133 TIME

hence realTOTime and timeToReal are inverses of each other when defined. Raises Overflow if t is not representable as a real.

[fmt n t] returns as a string the number of seconds represented by t, rounded to n decimal digits. If n <= 0, then no decimal digits are reported.

[toString t] returns as a string the number of seconds represented by t, rounded to 3 decimal digits. Equivalent to (fmt 3 t).

[fromString s] returns SOME t where t is the time value represented by the string s of form [\n\t ]\*([0-9]+(\.[0-9]+)?)|(\.[0-9]+); or returns NONE if s cannot be parsed as a time value.

[scan getc src], where getc is a character accessor, returns SOME (t, rest) where t is a time and rest is rest of the input, or NONE if s cannot be parsed as a time value.

[+] adds two time values. For reals r1, r2 >= 0.0, it holds that realToTime r1 + realToTime r2 = realToTime(Real.+(r1,r2)). Raises Overflow if the result is not representable as a time value.

[-] subtracts a time value from another. That is, tl - t2 is the duration from t2 to tl. Raises Time if tl < t2 or if the result is not representable as a time value. It holds that t - zeroTime = t.

[<]
[<=]
[<=]
[>=] compares time values. For instance, for reals r1, r2 >= 0.0
it holds that realToTime r1 < realToTime r2 iff Real.<(r1, r2)</pre>

[compare(t1, t2)] returns LESS, EQUAL, or GREATER, according as t1 precedes, equals, or follows t2 in time.

TIMER TIMER

# Module Timer

Timer -- SML Basis Library

[opu\_timer] is the type of timers for measuring CPU time consumption (user time, garbage collection time, and system time).

[real\_timer] is the type of timers for measuring the passing of real time (wall-clock time).

startCPUTimer ()] returns a cpu\_timer started at the moment of he call.

[totalCPUTimer ()] returns a cpu\_timer started at the moment the library was loaded.

[checkCPUTimer tmr] returns {usr, sys, gc} where usr is the amount of user CPU time consumed since tmr was started, gc is the amount of user CPU time spent on garbage collection, and sys is the amount of system CPU time consumed since tmr was started. Note that gc time is included in the usr time. Under MS DOS, usr time and gc time are measured in real time.

[startRealTimer ()] returns a real\_timer started at the moment of the call.

 [checkRealTimer tmr] returns the amount of real time that has passed since tmr was started.

UNIX

135

# Module Unix

```
Unix -- SML Basis Library
```

type proc type signal = Signal.signal

```
val executeInEnv : string * string list * string list -> proc
val execute : string * string list -> proc
val streamsof : proc -> TextLO.instream * TextLO.outstream val kill : proc * signal -> unit val kill : proc * process.status val reap
```

This structure allows Moscow ML programs to start other processes and to communicate with them.

Child processes are not automatically terminated when the parent (MM) process terminates. To forcibly terminate a child process pruse Unix.kill(pr, Signal.term). Then, to remove the terminated process from the operating system tables, call Unix.reap(pr).

The protocol for communication between the ML program and its child process must be designed with some care, typically using non-blocking input for reading from the child process.

[proc] is the type of processes started by the ML program.

[signal] is the type of Unix-style signals, which can be sent to another process. Signal values must be obtained from the Signal structure.

[execute (cmd, args)] asks the operating system to execute the command cmd with the argument list args, as a separate process. Two pipes connected to the standard input and standard output of the new process are created; these may be obtained using streamsOf. A proc value representing the new process is returned. The new process executes using the same environment as the calling process. Raises Fali in case of failure, e.g. if the process or the pipes cannot be created.

Typically, the cmd argument will be the full pathname of an executable. On Unix systems, simple command searching as done by the shell, allowing cmd to be a relative pathname, can be achieved by using

execute("/bin/sh", "-c" :: concat (cmd :: " " :: args))

[executeInEnv (omd, args, env)] asks the operating system to execute the command cmd with the argument list args in the envisonment env, as a separate process. Returns a proc value representing the new process. Typically, a string in the env list has the form "NAME=VALUE". See also Process getEnv:

[streamsOf pr] returns a pair (ins, outs) of input and output streams associated with process pr. The standard output of pr is the source for the input stream ins, and the standard input of pr is the sink for the output stream outs.

[reap pr] closes the input and output streams associated with pr, and then suspends the current (ML) process until the process corresponding to pr terminates. Returns the exit status given by pr when it terminated. Raises Fail in case of failure, e.g. if pr has already been reaped.

Under Unix, information about a terminated process remains in the system tables until the process is reaped. Thus, an ML program using execute or executeInEnv must make sure to reap any process it has created, or else the system tables will fill up.

[kill (pr, s)] sends the signal s to the process pr. Raises Fail in case of failure, e.g. if pr has already been killed.

# Module Vector

```

['ty vector] is the type of one-dimensional, immutable, zero-based constant-time-access vectors with elements of type 'ty.

Type 'ty vector admits equality if 'ty does. Vectors v1 and v2 equal if they have the same length and their elements are equal.

[maxLen] is the maximal number of elements in a vector.

[fromList xs] returns a vector whose elements are those of Raises Size if length xs > maxLen.

Raises [tabulate(n, f)] returns a vector of length n whose elements are f 0, f 1, ..., f (n-1), created from left to right. Rais Size if n<0 or n>maxLen.

[length v] returns the number of elements in v.

[sub(v, i)] returns the i'th element of v, counting from 0. Raises Subscript if i<0 or i>=length v.

[extract(v, i, NONE)] returns a vector of the elements v[i..length v-1] of v. Raises Subscript if i<0 or i>length v.

[extract(v, i, SOME n)] returns a vector of the elements v[i..i+n-1] of v. Raises Subscript if i<0 or n<0 or i+n>length v.

[concat vs] returns a vector which is the concatenation from left to right og the vectors in vs. Raises Size if the sum of the sizes of the vectors in vs is larger than maxLen.

That is, [fold] f e v] folds function f over v from left to right. computes f(v[ln-1], f(v[ln-2], ..., f(v[1], f(v[0], e)) where len is the length of v.

That is, [foldr f e v] folds function f over v from right to left. computes  $f(v[0], f(v[1], \ldots, f(v[len-2], f(v[len-1], e)))$  where len is the length of v.

app f v] applies f to v[j] for j=0,1,...,length v-1.

[map f v] applies f to v[j] for j=0,1,...,length v-1 and new vector containing the results.

The following iterators generalize the above ones in two ways:

\* the index j is also being passed to the function being iterated;

VECTOR

137

\* the iterators work on a slice (subvector) of a vector.

That is The slice (v, i, SOME n) denotes the subvector v[i..i+n-1]. That i v[i] is the first element of the slice, and n is the length of the slice. Valid only if 0 <= i <= i+n <= length v. The slice (v, i, NONE) denotes the subvector  $v[i..length\ v-1]$ . That is, the slice denotes the suffix of the vector starting at i. Valid only if  $0 <= i <= length\ v$ . Equivalent to  $(v, i, SOME(length\ v-i))$ 

	v[0len-1] v[0n-1] v[ilen-1] v[ii+n-1]
	(suffix)
meaning	the whole vector a left subvector ( a right subvector a general slice
slice	(v, 0, NONE) (v, 0, SOME n) (v, i, NONE) (v, i, SOME n)

[foldlif e (v, i, SOME n)] folds function f over the subvector  $v[i.:i_{n-1}]$  from left to right. That is, computes  $f(i_{n-1}, v[i_{n-1}], f(..., f[i_{n-1}, v[i_{n-1}], f(i), v[i]))$ . (i, v[i]), f(i,v[i], v[i]).

[foldli f e (v, i, NONE)] folds function f over the subvector v[i..den\_1] from left to right, where len = length v. That is, computes f(len-1, v(len-1), f(..., f(i+1, v[i+1], f(i, v[i], e)) Raises Subscripti f i <0 or i > length v.

[foldri f e (v, i, SOME n)] folds function f over the subvector v[i.:4n-1] from right to left. That is, computes f(i, v[i], f(i+1, v[i+1], ..., f(i+n-1, v[i+n-1], e) ...)). Raises Subscript if ie0 or ne0 or in > length v.

[foldri f e (v, i, NONE)] folds function f over the subvector v[i.len-l] from right to left, where len = length v. That is, computes f[i, v[i] f[i1, v[i1]], ..., f[len-l, v[len-l], e) ...)). Raises Subscript if i<0 or i > length v.

appi f (v, i, SOME n)] applies f to successive pairs (j, v[j]) for  $j=i,i+1,\ldots,i+n-1$ . Raises Subscript if i<0 or n<0 or i+n > length v.

(appi f (v, i, NONE)] applies f to successive pairs (j, v[j]) for
j=i,i+1,...,len=1, where len = length v. Raises Subscript if i<0
or i > length v.

[mapi f (v, i, SOME n)] applies f to successive pairs (j, v[j]) for j=i,i+1,...,i+n-1 and returns a new vector (of length n) containing the results. Raises Subscript if i<0 or n<0 or i+n > length v.

[mapi f (v, i, NONE)] applies f to successive pairs (j, v[j]) for j=1,i+1,...,len-1, where len = length v, and returns a new vector (of length len-i) containing the results. Raises Subscript if i<0 or i > length v.

['a weak] is the type of weak pointers to objects of type 'a. A weak pointer is a pointer that cannot itself keep an object alive. Hence the object pointed to by a weak pointer may be deallocated by the garbage collector if the object is reachable only by weak pointers. In this case, subsequent accesses via the 'get' function will raise Fail "Dangling weak pointer". (We raise an exception instead of returning an option value, because access via a weak pointer to a deallocated object is likely to be a programming Integers, characters, words and booleans will not be deallocated by the garbage collector and will remain reachable forever by a weak pointer. Reals, strings, tuples and other non-nullary constructors may be deallocated by the garbage collector. Constants, even composite ones, will not be deallocated either.

[weak v] creates and returns a weak pointer to value v.

[get w] returns the value pointed to by weak pointer w, if the value is still alive. Otherwise raises Fail "Dangling weak pointer"

[set(w, v)] makes the weak pointer w point to the value v.

[isweak w] returns true if the value pointed to by w is dead; returns false otherwise. If an object is reported to be dead, it remains dead. However, an object is reported to be live just if it has not yet been deallocated by the garbage collector. The allocation of any new value may activate the garbage collector and

cause the object to die. Thus if not (isweak w) then get w else "blah" if not raise exception Fall, whereas the following might: if not (isweak w) then ([1.2] @ [3.4]; get w) else "blah" because evaluation of the list append may cause w to die.

The value of isweak w is the same as that of

(get w; false) handle Fail \_ => true
but evaluating the latter expression may have the side effect o
keeping w alive for slightly longer, because a pointer to w is

WEAK

returned by get w.

Jo ['a array] is the type of arrays of weak pointers to objects

efficient than, a one-element 'a Weak array. On the other hand, an 'a Weak array is more efficient than an ('a Weak weak) Array array. A value of type 'a Weak.weak (above) is equivalent to, but more

[array n] creates an array of n weak pointers. Initially, any access to the array will raise Fail.

[sub(a, i)] returns the object pointed to by cell i (counting from 0) of the array a, if it is live. Raises Fail "Dangling weak pointer" if cell i has never been updated or if the object pointed to has been deallocated by the garbage collector. Raises Subscript if i<0 or i>=length a. To make sub' infix, use the declaration infix 9 sub

to [update(a, i, v)] updates cell i of array a to point (weakly) the value v. Raises Subscript if i<0 or i>=length a. [isdead(a, i)] returns true if the object in cell i of array a is dead, and false otherwise. Analogous to isweak; see above

[length a] returns the number of elements in a.

[maxLen] is the maximal number of elements in an array.

The iterators described below operate on the live elements only. Note that an element a[k] may die in the course of folding f over earlier elements (e,g,a[1]) ... a[k-1]). Thus the functions should be used with great care.

fold I fe a folds function fover the live elements of a, from eft to right

[foldr f e a] folds function f over the live elements of a, from right to left.

app f al applies f to the live elements of a from left to right.

[modify f a] applies f to a[j] and updates a[j] with the result f(a[j]), for each live element a[j], from left to right.

The following iterators generalize the above ones in two ways:

. the index j is also being passed to the function being iterated: . the iterators work on a slice (subarray) of an array.

The slice (a, i, SOME n) denotes the subarray a[i..i+n-1]. That is, a[i] is the first element of the slice, and n is the length of the slice. Valid only if 0 <= i <= i+n <= length a.

The slice (a, i, NONE) denotes the subarray a[i..length a-1]. That is, the slice denotes the suffix of the array starting at i. Valid only if 0 <= i <= length a. Equivalent to (a, i, SOME(length a - i)).

	a[0len-1] a[0n-1] a[ilen-1] a[ii+n-1]
meaning	the whole array a left subarray (prefix) a right subarray (suffix) a general slice
ge	0, NONE) 0, SOME n) i, NONE) i, SOME n)
slic	(a,

[foldli f e (a, i, SOME n)] folds function f over the live elements of the subarray a[i...i+n-1] from left to right. Raises Subscript

WEAK 140

if i<0 or n<0 or i+n > length a.

[foldli f e (a, i, NONE)] folds function f over the live elements of the subarray a[i..len-1] from left to right, where len = length a. Raises Subscript if i<0 or i > length a.

[foldrif e (a, i, SOME n)] folds function f over the live elements of the subarray a[i..i+n-1] from right to left. Raises Subscript if i<0 or n<0 or i+n > length a.

[foldrif e (a, i, NONE)] folds function f over the live elements of the subarray a[i..len-1] from right to left, where len = length a. Raises Subscript if i<0 or i > length a.

[appi f (a, i, SOME n)] applies f to successive pairs (j, a[j]) for j=i,i+1,....i+n-1, provided a[j] is live. Raises Subscript if i<0 or n<0 or i+n > length a.

[appi f (a, i, NONE)] applies f to successive pairs (j, a[j]) for j=i,i+1,...,len-1, where len = length a, provided a[j] is live. Raises Subscript if i<0 or i > length a.

[modifyi f (a, i, SOME n)] applies f to (j, a[j]) and updates a[j] with the result f(j, a[j]) for j=i,i+l,...,i+n-1, provided a[j] is live. Raises Subscript if i<0 or n<0 or i+n > length a.

[modifyi f (a, i, NONE)] applies f to (j, a[j]) and updates a[j] with the result f(j, a[j]) for j=i,i+1,...,len-1, provided a[j] is live. Raises Subscript if i<0 or i > length a.

141 WORD

### Module Word

Word -- SML Basis Library

type word = word

: int

val wordSize

| \* word -> word | \* word -> word | \* word -> word word -> word : word word val orb val andb val xorb

-> word -> word word \* word word \* word word \* word word \* word -× ^ ? val val val val val

-> word -> word -> word -> word word word word div

val toStri val fromSt val scan

toString : word -> string fromString : string -> word option scan : StringCvt.radix -> (char, 'a) StringCvt.reader -> (word, 'a) StringCvt.reader fmt : StringCvt.radix -> word -> string val

with sign extension : word -> int
: word -> int
: int -> word toInt toIntX fromInt val val

with sign extension with sign extension val toLargeWord : word -> word val toLargeWordX : word -> word val fromLargeWord : word -> word : word -> int
: word -> int
: int -> word . toLargeInt . toLargeIntX . fromLargeInt val val [word] is the type of n-bit words, or n-bit unsigned integers.

In Moscow ML, n=31 on 32-bit [wordSize] is the value of n above. machines and n=63 on 64-bit machines.

[orb(w1, w2)] returns the bitwise 'or' of w1 and w2.

[andb(w1, w2)] returns the bitwise 'and' of w1 and w2

[xorb(w1, w2)] returns the bitwise 'exclusive or' or w1 and w2.

[notb w] returns the bitwise negation of w.

 $[<<(w,\ k)]$  returns the word resulting from shifting w left by k bits. The bits shifted in are zero, so this is a logical shift. Consequently, the result is 0-bits when k >= wordSize.

[>(w, k)] returns the word resulting from shifting w right by k bits. The bits shifted in are zero, so this is a logical shift. Consequently, the result is 0-bits when k >= wordSize.

[->>(w, k)] returns the word resulting from shifting w right by k bits. The bits shifted in are replications of the left-most bit: the 'sign bit', so this is an arithmetical shift. Consequently, for k >= wordSize and wordToInt w >= 0 the result is all 0-bits, and for k >= wordSize and wordToInt w < 0 the result is all 1-bits.

To make <<, >>, and ~>> infix, use the declaration infix 5 << >> ~>>

[+]
[4]
[4]
[4]
[4]
[mod] represent unsigned integer addition, subtraction, multiplication, division, and remainder, modilus 2 raised to the n'th power, where n=wordSize. The operations (i div j) and (i mod j) raise biv when j=0. Otherwise no exceptions are raised.

[<]
[<=]
[>>]
[>=] compare words as unsigned integers.

[compare(w1, w2)] returns LESS, EQUAL, or GREATER, according as w1 is less than, equal to, or greater than w2 (as unsigned integers).

[min(w1, w2)] returns the smaller of w1 and w2 (as unsigned integers).

 $\max(w1,\ w2)$ ] returns the larger of w1 and w2 (as unsigned integers).

[fmt radix w] returns a string representing w, in the radix (base) specified by radix.

output format [0-9A-F]+ [0-9](base 2) (base 8) unsigned decimal (base 10) unsigned hexadecimal (base 16) unsigned binary unsigned octal description radix BIN OCT DEC

[toString w] returns a string representing w in unsigned hexadecimal format. Equivalent to (fmt HEX w).

[fromString s] returns SOME(w) if a hexadecimal unsigned numeral can be scanned from a prefix of string s, ignoring any initial whitespace; returns NONE otherwise. Raises Overflow if the scanned number cannot be represented as a word. An unsigned hexadecimal numeral must have form, after possible initial whitespace: [0-9a-fA-F]+

[scan radix getc charsrc] attempts to scan an unsigned numeral from the character source charsrc, using the accessor getc, and ignoring any initial whitespace. The radix argument specifies the base of the numeral (BIN, OCT, DEC, HEX). If successful, it returns SOME(w, rest) where w is the value of the numeral scanned, and rest is the unumed part of the character source. Raises Overflow if the have form, after possible initial whitespace:

(0wx | 0wX | 0x | 0x)? [0-9a-fA-F]+(0w)?[0-1]+ (0w)?[0-7]+ input format radix BIN OCT DEC toInt w] returns the (signed) integer represented by bit-pattern w. toIntX w] returns the (signed) integer represented by bit-pattern w. fromInt i] returns the word representing integer i.

[toLargeInt w] returns the (signed) integer represented by bit-pattern w. [toLargeIntX w] returns the (signed) integer represented by bit-pattern w.

[fromLargeInt i] returns the word representing integer i.

143

[toLargeWordX w] returns w. [fromLargeWord w] returns w. toLargeWord w] returns w.

```

[word] is the type of 8-bit words, or 8-bit unsigned integers the range 0..255.

with sign extension

with sign extension

toLargeWord : word -> Word.word toLargeWordX : word -> Word.word fromLargeWord : Word.word -> word

val val

fromLargeInt

wordSize] equals 8.

[orb(w1, w2)] returns the bitwise 'or' of w1 and w2

[andb(w1, w2)] returns the bitwise 'and' of w1 and w2

w2. [xorb(w1, w2)] returns the bitwise 'exclusive or' or w1 and

notb w] returns the bitwise negation of w.

 $[<<(w,\ k)]$  returns the word resulting from shifting w left by k bits. The bits shifted in are zero, so this is a logical shift. Consequently, the result is 0-bits when k >= wordSize.

[>(w, k)] returns the word resulting from shifting w right by k bits. The bits shifted in are zero, so this is a logical shift. Consequently, the result is 0-bits when k >= wordSize.

145

[->>(w, k)] returns the word resulting from shifting w right by k bits. The bits shifted in are replications of the left-most bit: the 'sign bit', so this is an arithmetical shift. Consequently, for k >= wordSize and wordTont w >= 0 the result is all 0-bits, and for k >= wordSize and wordTont w < 0 the result is all 1-bits.

To make <<, >>, and ~>> infix, use the declaration: infix 5 << >> ~>>

[mod] represent unsigned integer addition, subtraction, multiplication, division, and remainder, modulus 256. The operations (i div j) and (i mod j) raise Div when j = 0. Otherwise no exceptions are raised. [div]

\[ \]

>=] compare words as unsigned integers.

[compare(w1, w2)] returns LESS, EQUAL, or GREATER, according as w1 is less than, equal to, or greater than w2 (as unsigned integers).

[min(w1, w2)] returns the smaller of w1 and w2 (as unsigned integers).

[max(w1, w2)] returns the larger of w1 and w2 (as unsigned integers).

[fmt radix w] returns a string representing w, in the radix (base) specified by radix.

radix	description	no.			output tormat
				i	
BIN	unsigned	binary	(base	2)	[01]+
OCT	unsigned	octal	(base	8	+[0-1]
DEC	unsigned	decimal	(base	10)	+[6-0]
HEX	unsigned	hexadecimal	(base	16)	[0-9A-F]+

toString w] returns a string representing w in unsigned hexadecimal format. Equivalent to (fmt HEX w). [fromString s] returns SOME(w) if a hexadecimal unsigned numeral can be scanned from a prefix of string s, ignoring any initial whitespace, returns NONE otherwise. Raises Overflow if the scanned number cannot be represented as a word. An unsigned hexadecimal numeral must have form, after possible initial whitespace: [0-9a-fA-F]+

[scan radix {getc} charsrc] attempts to scan an unsigned numeral from the character source charsrc, using the accessor getc, and ignoring any initial whitespace. The radix argument specifies the base of the numeral (BIN, OCT, DEC, HEX). If successful, it returns SOME(w, rest) where w is the value of the numeral scanned, and rest is the unused part of the character source. Raises Overflow if the scanned number cannot be represented as a word. A numeral must have form, after possible initial whitespace:

(0wx | 0wX | 0x | 0x)? [0-9a-fA-F]+(0w)?[0-1]+ (0w)?[0-7]+ input format radix BIN

[toInt w] returns the integer in the range 0..255 represented by

toIntX w] returns the signed integer (in the range ~128. represented by bit-pattern w. [fromInt i] returns the word holding the 8 least significant bits of

[toLargeInt w] returns the integer in the range 0..255 represented by w.

[toLargeIntX w] returns the signed integer (in the range  $\sim 128..127$ ) represented by bit-pattern w. [fromLargeInt i] returns the word holding the 8 least significant bits of i.

[toLargeWord w] returns the Word.word value corresponding to w.

[toLargeWordX w] returns the Word.word value corresponding to w, with sign extension. That is, the 8 least significant bits of the result are those of w, and the remaining bits are all equal to the most significant bit of w: its 'sign bit'.

[fromLargeWord w] returns w modulo 256.

Module Word8Array

WORD8ARRAY

147

Word8Array -- SML Basis Library

eqtype array

type elem = Word8.word type vector = Word8Vector.vector : int val maxLen

val array : int \* elem -> array
val tabulate : int \* (int -> elem) -> array
val fromList : elem list -> array

val length val sub val update val extract : {src: array, si: int, len: int option, dst: array, di: int, >- unit src: vector, si: int, len: int option, dst: array, di: int} -- unit val copyVec val copy

[array] is the type of one-dimensional, mutable, zero-based constant-time-access arrays with elements of type Word8 word, that is, 8-bit words. Arrays a Zare equal if both were created by the same call to a primitive (array0, array, tabulate, fromList).

All operations are as for Array.array.

```

[vector] is the type of one-dimensional, immutable, zero-based constant-time-access vectors with elements of type Word8.word, that is, 8-bit words. Type vector admits equality, and vectors v1 and v2 are equal if they have the same length and their elements are equal.

All operations are as for Vector.vector.
